OTO-MASSAGE IN SUPPURATION OF THE EAR ITS VALUE FOR THE RELIEF OF DEAFNESS AND IN THE TREATMENT OF THE SUPPURATION

Read by title in the Section on Laryngology and Otology at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta, Ga, May 5-8 1896

BY LOUIS J LAUTENBACH, A M, M D, Ph D
Surgeon to the Pennsylvania Eye and Ear Infirmary Nose and Throat Physician to the Odd Fellows Home Late Chief of the Eye Clinic of the German Hospital, etc
PHILADELPHIA PA

Upon several occasions I have presented various aspects of oto-massage, but, beyond having noted in one of my papers that I considered the deafness occasioned by suppurative disease of the middle ear peculiarly favorable in its reaction to massage, I have not publicly considered suppurative disease in connection with the subject I have often been asked the value of the method in the deafness and tinnitus, the results of suppurative disease On expressing my opinion that it was of especial value in both conditions, I have naturally been lead to explain why this was the case

In considering the value of massage in the treatment of cases of suppurative disease or of the defects from suppurative disease, the subject naturally divides itself into two parts 1, the consideration of its application and value *in cases undergoing suppuration*, 2, its importance in those in which the suppuration has ceased, deafness being present with or without tinnitus

Eliminating for the present all the acute suppurative cases, those attended with extreme pain and swelling of the parts, we will study a typical case of chronic suppurative disease It will present, in addition to the discharges, which may be meagre or profuse, watery or ropy, colorless, pustular or bloody, a greater or less degree of deafness with or without tinnitus, accompanied usually by a *full or swollen feeling* within the ear, with perhaps a little tenderness and with occasional attacks of pain

The usual treatment for such cases has been careful cleansing of the meatus and middle ear, usually by syringing with warm or medicated water, followed occsionally by cleansing with peroxid of hydrogen solution, and then after thoroughly drying the ear with cotton and perhaps using the Politzer bag or the Siegle speculum, or both, the insufflation of some drying or absorbent powder, such as aristol, iodoform or boracic acid The ordinary mild cases are apt to do fairly well under such routine treatment, especially if it be persisted in, and they often develop a decided improvement in hearing, as well as a marked diminution and, frequently, an entire cessation of the ear discharges

In contradistinction to this the dry method is used by many The meatus is carefully wiped out with cotton, after which, if a probe can be passed through the perforation the middle ear is cleansed as thoroughly as possible Then by means of the Politzer air bag and Siegle speculum, the discharges lying low down in the ear are forced toward and through the perforation in the membrane and the middle ear and meatus are again cleansed with dry cotton, after which drying powders are used

An objection to be urged against the first method above outlined is the syringing of the ear In my opinion this, in many cases, prevents the cessation of the discharge, the water or medicated liquid finds its way into the deeper parts of the ear and not being removed, lies there and acting as a foreign substance, excites irritation and inflammation in the surrounding tissues and thus increases the amount of the discharge Of late, the dry method has come more and more into vogue It has the advantage of removing foreign matters from the ear cavity without subjecting the ear to the possible disadvantages of having the pus replaced by other foreign particles But both methods fail in entirely removing the exudated materials from the middle ear cavity—the former method washing out much of the discharge and diluting the rest—the latter removing considerable but allowing some of the discharge to lie on the floor of the tympanum, as well as leaving a layer of the discharge adherent to all the surfaces and an especially large amount to remain in the attic and on the ossicular structures In these cases to remove the discharges which otherwise are irremovable I employ massage instruments, using them as cleansers and dryers of the middle ear cavity To illustrate this method of using massage I will briefly outline the treatment of an average case of middle ear disease with suppuration Finding that I am dealing with a case of suppuration of the chronic type, I dry out the meatus with a cotton-covered probe and if the perforation in the drumhead be sufficiently large to allow of it, I by the same means cleanse the middle ear as much as I am able, then by the Siegle speculum I suck out as much of the pus as possible and dry the meatus once more, then I inflate with the Politzer bag and force out a little more discharge, which I remove with the dry cotton I then apply to the patient a pneumo-massage apparatus of medium strength and gradually increase the suction I succeed in drawing into the meatus and about the perforation of nearly, if not, all of the discharge which may have adhered to the crypts and along the walls of the middle ear After drying with cotton, I once more use the pneumo-masseur and again dry, after which I use the drying powders or astringent antiseptics, if any of these be neccessary If the ear discharge be too thick or too firm for removal in this manner I then soften the discharge by the use of 3 per cent solution peroxid of hydrogen, after which I proceed as above outlined

In using the pneumo-masseur for the purpose of removing the adherent discharges from the middle ear cavity, I try to use it as forcibly as necessary without in any way imperiling the integrity of the structures, especially avoiding the production of any hemorrhage. I have found by experience that I can usually commence with an exhaust pressure of two ounces to the square inch and gradually increase it to about half a pound to the square inch, often as much as a pound, and rarely up to two pounds to the inch. With an exhaust from half a pound to a pound, the discharges are usually quickly removed, in from three to ten minutes, 300 or less strokes per minute usually sufficing.

Previous to my using the metronomic masseurs, I endeavored to accomplish this same effective cleansing by the use of the Siegle speculum but, necessarily, the results were indifferent. Since I have used the pneumo-masseur in the manner described I find that I can stop the suppuration more quickly than formerly, and often accomplish this result without any therapeusis to the ear whatever. This, however, is not usually the case, and to a considerable extent I rely upon stimulating and drying powders in connection with thorough cleansing and drying.

In acute cases I apply the suction massage just as soon as is possible, believing that adhesions, ulcerations and destruction of the tissues result often from the pressure of the discharge, from its direct corrosive effect and its fermentative results as well as from the progress of the inflammatory affection.

As soon as the pain is sufficiently allayed so that the treatment is bearable, I apply to the ear either the *metronomic ear masseur or a little electric suction* pump and clear the middle ear of all its discharges and accumulations. By securing a clean surface early in the course of the disease I hasten reparative action and avoid the ofttimes destructive effects of the decomposition of unhealthy pus.

These ear discharges lying in the middle ear, envelop the ossicles, fill up the space between the promontory and the membrane, and generally occupy all possible spaces, gluing all together. As a result of this we have occasioned abnormal adhesions between the ossicles and between the ossicles and the surrounding walls, as well as occasionally ligamentous bands between the membrane and surrounding structures, again, in other cases, the disease results not in a tying together of the various parts, but a rending asunder of normal structures, in ulcerations, necroses and sloughings.

In the one case we have anchyloses, adhesions, abnormal growths and thickenings followed often by sclerotic changes, in the other we have necrotic changes with often loss of one or more of the ossicles or greater destruction of the tympanic membrane or ulceration of the mucous lining of the middle ear with inflammation extending, perhaps, into the mastoid or involving the internal ear. It is on account of these often serious results that there is an urgent necessity for prompt action, with the idea of restoring the parts as soon as possible to as nearly a normal condition as can be attained. It is therefore necessary if anything can be gained by pneumo massage, to apply it as early as is admissible.

In some cases I have used the masseur during the acute stage of the attack with marked benefit, allaying the pain and for the time being increasing the amount of suppuration and apparently shortening the attack. I presume the reason for this is that much of the pain in these cases is occasioned by the retention of the discharges, the tissues being filled with discharges which, finding no outlet, have commenced to burrow more and more deeply, the infiltration ever extending and when the pressure from the central inflammatory area is released by means of the exhaust apparatus, the tissues adjoining empty themselves of their contained discharges, thus relieving much of the abnormal tension of the surrounding infiltrated zone, the lessening of the pressure relieving the pain, and the frequent application of the method tending to prevent extension of the inflammation.

From my experience with this method of cleansing the ear, I am convinced that there would be fewer cases of secondary involvement of the internal ear if the practice above outlined was more generally followed. When we consider that the cases of internal ear disease are the most difficult and unsatisfactory with which the ear surgeon has to deal, the necessity of their avoidance is evident. I know of no other measure of relief which exercises such a powerful influence in the avoidance of this complication.

I very much desire to go more deeply into the subject and illustrate it by cases, but I find this to be impossible as I wish to refer to another aspect of the matter, the improvement in hearing brought about by oto-massage in suppurative cases as well as in cases of deafness occasioned by suppurative disease.

Strange as it may seem, I have found in no class of my chronic ear cases such marked improvement of impaired hearing as in those in which the defect was caused by suppuration. Sclerotic changes are rare in these cases until long after the subsidence of the suppurative disease. I will refer to two such cases of deafness, the result of suppurative disease. Two years ago I reported the case of a woman 38 years old who had scarlet fever in her first year. When I saw her the ears were discharging and there was very poor hearing power. After she had been using the massage treatment for some months, not only did the discharge stop, but the hearing improved so much that she had no conscious difficulty in hearing conversation, the watch being heard twenty inches ($\frac{20}{52}$) from the ear. The progress of this case was a steady gain in hearing power from the commencement. From the time of my report to the present there has been no diminution in hearing power.

I will briefly note another case. Miss C. M., 15 years old came to me Dec. 1, 1894, for chronic suppurative disease of the left ear. There was a large perforation and a fair amount of whitish discharge, not very gluey. There was no watch hearing on contact. I treated her ear without massage and succeeded in about four months in stopping the suppuration but the perforation did not heal. I endeavored during another two months to heal the perforation, without success. The hearing distance had improved at this time to hard contact hearing for the watch. I then endeavored to restore the hearing by means of massage, using the pneumo-masseur, but especially the phono-masseur, neglecting the perforatian, hoping it would heal spontaneously. Now, after ten months of such treatment (one visit per week), she hears the watch at ten inches, the perforation remaining unhealed.

In these cases the two kinds of *massage* are valuable—the *phono* to stimulate the nerve, which is more easily accomplished in such cases by reason of the perforation allowing the sound to be carried more directly to the internal ear—the pneumo-masseur being used to break down adhesions and restore abnormal or diseased parts to more healthy action by reason of the stimulation thus produced

To indicate the value of phono-massage, the following experiment will serve April 26, 1896, I tested the hearing of the right ear of Mr C M , aged 28, and found it to be for the watch one-quarter inch His is a case of old suppuration with bone involvement—one which has gone on for twelve or fifteen years and which he thought was incurable The strong phono-masseur was used on his ear for forty minutes with the result that the hearing for the watch was increased to one and one-quarter inches This increased hearing usually gradually disappears unless the treatment is regularly applied If this be done it usually increases, the amount depending on the nature of the case This immediate increase in hearing is a very frequent experience in my work, and one which I usually secure except where there has been most extensive destruction of the middle or internal ear structures In dry suppurative cases where I do not succeed in producing an almost immediate temporary increase in hearing distance, my conclusion is that permanent results are very difficult to attain

In conclusion the facts may be summed up as follows In acute suppurative conditions, pneumo-massage should be tried and if the application be not too painful it will relieve the swelling and the severity of the inflammatory pain and shorten the attack, the purpose of this suction massage being to remove from the ear all possible suppuration and thus, by relieving the tension, lessening the frequency of ulcerations and necrotic processes and preventing adhesions and deep infiltrations of the surrounding tissues

In cases of suppuration that have passed the acute stage the pneumo-masseur is to be used for the purpose of relieving the ear of its discharges and for the relief of extreme tension, preventing ulcerations and necroses, as well as to overcome the formation of adhesions and for the stretching, absorption and destruction of these adhesions when formed, and to stimulate the drumhead and its connecting structures to normal, functional action The phono masseur is to be used in these cases for the purpose of restoring to the ear nerve and its terminals the normal tone and overcoming the sluggishness to response engendered by inaction and disease

In cases of deafness following upon suppurative disease the pneumo-massage is useful for limbering up the diseased and stiffened tissues, to restore their normal action and tone, and to break or stretch abnormal adhesions, to overcome anchylosed joints and give to the ossicles their normal motion, while at the same time improving the circulation of all the middle ear structures—the phono-massage being again used for its effect upon a sluggish, diseased and non-responsive nerve ending

Intravenous Injections of Sublimate in Ocular Affections —Angelucci has found rapid and thorough recovery follow the use of intravenous injections of 20 centigrams of sublimate and 60 centigrams of chlorid of sodium, in 100 grams of distilled water The dose increasing from 2 to 16 milligrams The cases favorably affected were all of syphilitic origin Iritis, irido choroiditis, papillo retinitis, etc , but the results were negative in all non syphilitic troubles —*Revue Gén d'Ophth* , August 31, from *Arch di Ottalm* No 3

STRICTURE OF THE UPPER PORTION OF THE TRACHEA SUCCESSFULLY TREATED BY DIVULSION THROUGH THE LARYNX

Read in the Section on Laryngology and Otology at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga May 5 8 1896

BY JOHN O ROE, M D
ROCHESTER N Y

The following case of stricture of the upper part of the trachea, due to organic contraction, can not, on account of its rarity, fail to be of interest

On November 23, 1895, Miss D , aged 27 years, was referred to me on account of frequent and urgent attacks of dyspnea, which had for a considerable time been exceedingly distressing to her She gave the following history In March, 1888, she had a severe attack of diphtheria, from which it was thought at the time she had fully recovered During the following year, however, it was noticed that she had edema of the feet The edema was found to be associated with albuminuria and was ascribed to that cause Notwithstanding this she enjoyed a fair degree of health

In October, 1890, she became hoarse nearly every day as evening came on This hoarseness continued until December, when she began to have considerable difficulty in breathing The family physician found a swollen condition of the larynx, which he regarded as a consequence of the albuminuria He treated her with steam inhalations, compelling her to remain in bed for about three months continuously with the object of maintaining a uniform temperature and preventing her from contracting cold During this time her health was very good and she gained ten or twelve pounds in weight, although she had one or two severe attacks of dyspnea, lasting three or four days at a time These were attributed entirely to the renal disturbance, since albumin and casts were found in the urine

After a time the dyspnea subsided and in April, 1891, she began to go out Shortly after, however, she took cold, and had another severe attack of dyspnea, lasting several days As warm weather came on her dyspnea disappeared Her voice during the period, since her first attack of hoarseness, had remained quite clear

In August, 1891, she went to Canada and remained there until fall, feeling quite well She continued to feel quite well during the fall, but during the winter she had frequent attacks of dyspnea, very similar to those of previous winters During the following summer she had no special difficulty in breathing, although during July, August and September she was aphonic

During the fall of 1892, she had at times much difficulty in breathing, and that winter she spent in Southern Pines, South Carolina, where she gained much in general health Her breathing, however, was not materially improved, although the atmosphere there was remarkably dry She came home May 1, 1893, and during the following summer was quite well, having little or no difficulty in breathing

During August the cartilaginous portion of her nose began to diminish in size and for about a year afterward there was a gradual settling of this portion of the nose During November, 1894, she had inflammation of the right lung, which nearly proved fatal and very much increased her difficulty in breathing

During the following winter her dyspnea was frequently very urgent These attacks of dyspnea were aggravated very much by accumulations of mucous below the obstruction in the trachea, which she had great difficulty in expelling After expulsion of these accumulations her respiration was for a time very much improved As the warm weather came on, her dyspnea diminished, and during the summer of 1895 she was quite free from it, and felt very well As in previous years, when the cold weather came on, her trouble increased, and last October her dyspnea became very urgent, although her voice remained quite clear

On November 23, when she came under my care, there was found on examination a chronic subglottic laryngitis, with considerable infiltration of the subglottic region About three-fourths of an inch below the larynx there was an annular constriction, which appeared something like a membranous formation Notwithstanding the fact that no history of syphilis could be obtained, as the girl's character was beyond question, the sinking in of the nose appeared more or less positive evidence that the trouble was of a specific nature

Previous to the time that her nose began to diminish in size, her dyspnea was attributed entirely to the albuminuria, and she was treated accordingly, but after this manifestation it was thought that a specific trouble must be the cause of the difficulty Since it seemed so certain that it must be of that nature, I placed her upon an antisyphilitic treatment, in both large and small doses, but with no benefit whatever In fact, the dyspnea was aggravated by it, whereas iron and strychnia improved her condition

Locally I attempted to reduce the subglottic laryngitis by sprays and insufflation of a power composed of tannin, sugar of milk, and a small quantity of morphia This appeared to lessen the subglottic congestion, but had no effect in lessening the constriction in the trachea

On December 4, the dyspnea became so urgent that suffocation seemed imminent, necessitating either tracheotomy or intubation of the larynx The latter was resorted to and the tube was retained for two days, when it became so irritating as to require removal It had the effect, however, of so enlarging the constriction that the dyspnea for a considerable time entirely disappeared The constriction gradually returned, and in February it again became necessary to introduce the tube

As the tube was being introduced by the aid of the mirror, she suddenly threw her head forward, bringing the end of the tube quite forcibly against the anterior portion of the trachea As she jumped back, the tube was brought out She at once, however, experienced complete relief from her dyspnea and on the examination of her larynx, I found that the tube had broken down the anterior portion of the constriction so that the lumen of the anterior portion of the trachea was quite free

Seeing that this constriction could be disrupted, I introduced a pair of Grant's forceps, with blades closed, until they passed below the constriction I then opened the blades until the widest portion of them nearly filled the trachea Holding the handles firmly I drew the blades up in the constricted portion, so dilating it as to break down much of the posterior portion of the constriction and leave the trachea quite free As the glottis did not permit the forceps to open wide enough to fully break down the stricture, I had a pair of dilating forceps with double-jointed blades so constructed as to increase the expansion of the lower blades to the full width of the trachea and to completely obliterate the stricture

Since that time the constriction has shown little or no tendency to return An occasional dilatation of the trachea with the forceps is sufficient to maintain the opening The respiration and voice are quite normal By following up the dilatation of the trachea in this manner when there is a tendency of the constriction to return, I have every reason to believe that a permanent cure will be effected

This has been to me an exceedingly interesting case, being one of chronic subglottic laryngitis, to which was added *organic constriction* in the upper part of the trachea This case is of special interest on account of the uncertainty as to the exact cause of the condition, and also on account of the history of repeated attacks of dyspnea extending over so long a period

How much of this trouble we may ascribe to albuminuria, it is difficult to say We all recognize the condition of edema of the larynx and aphonia, associated with albuminuria, which we term albuminuric aphonia, and we know that specific taints uncontrolled by ordinary antispecific remedies may excite all sorts of conditions Subglottic laryngitis is a disease that is not of frequent occurrence, and is therefore not commonly met with in our daily work We know, however, that its cause is frequently involved in obscurity, although it is usually associated with lymphatic affections and the conditions termed scrofula, that it occurs usually in young females from fifteen to twenty-five years of age, and that the treatment which proved serviceable in this case is the one that is recognized as the most beneficial in simple chronic subglottic laryngitis Simple absorption of the tissues of the nose without ulceration results only, so far as I am aware, from a specific cause We must therefore believe even in the absence of every other manifestation that the underlying cause was a latent hereditary taint of a specific character which produced the subglottic laryngitis and ulceration of the upper portion of the trachea and the resulting stricture, as well as absorption of the tissues of the nose

DISCUSSION

Dr J E Logan, Kansas City, Mo —Is it not probable that this case is more or less of a specific type? The Doctor states that it was simply a settling of the cartilaginous septum unattended by any ulceration, and that the bony septum was intact This would make it a very peculiar and interesting case I have seen many of those cases which had no evidence of external ulceration, but there would be an ulcerated condition of the septum

A FEW REMARKS ON THE CLINIC USE OF ORTHO- AND PARA- CHLORO-PHENOL

Read in the Section on Laryngology and Otology at the Forty-seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5-8 1896

BY CONRAD BERENS, M D

ONE OF THE WILLS HOSPITAL SURGEONS PHILADELPHIA, PA

In the *University Medical Magazine* for October, 1894, there is a brief note of reference to ortho chloro phenol, quoting N Simanoffski, who is reported to have used it for reducing hypertrophies of the mucous membrane overlying the inferior turbinates of the nares Simanoffski made but a preliminary report, and referred also to para-chloro-phenol The endorse ment of ortho chloro-phenol was of such a nature that I was induced to make some trials with it, as well also as of para chloro-phenol Ortho chloro-phenol is a heavy limpid liquid of exceedingly irritating and pungent odor It is rapidly soluble for clinic purposes in glycerin, and from this may be reduced in strength again and made soluble in water For clinic purposes the para-chloro-phenol, which occurs in amorphous crystals, is best used by fusing to the end of a probe In my work I have fused the crystals to silver Para-chloro-phenol is not so satisfactory clinically, and is very much more cumbersome and inconvenient in its application The conclusions of Schourmo in regard to its irritating properties, particularly in laryngeal conditions, are fully borne out by clinic experience There is no denying the correctness of the statement of Spengler (*Brit Med Jour* 1896, No 1,827), as to its antiseptic properties, but I would take issue with him as to its efficacy compared with ortho-chloro phenol My experience having taught me that the latter is just as active an anesthetic, and is a very much more convenient form for clinic purposes The use of ortho-chloro-phenol for the reduction of engorgement of the erectile tissue overlying the inferior turbinates is much more satisfactory than the cautery—with less destruction of tissue and less intense reaction In acute engorgement of the erectile tissue, I have found nothing more satisfactory than its application by means of a small dossil of cotton dipped in the drug and applied antero-posteriorly to the parts after they have been prepared by the use of cocain The effect of the cocain having passed off after the thermo-electric cautery has been applied, patients as a rule complain of intense pain, and frequently of epistaxis, not to mention the enormous inflammatory swellings and frequent adhesions to the septum Ortho-chloro-phenol is slightly anesthetic, and this anesthesia is more persistent than that of cocain As a consequence after the action of the cocain has passed off that of the ortho-chloro-phenol continues, and the patient reacts without any inconvenience There being less inflammatory reaction it is natural that there should be less deeply seated initial lesions, but the drug has no place in the treatment of true hypertrophy, or hyperplasia of the region under discussion In ulcerous conditions more especially of the septum nasi, the application of the glycerole of ortho-chloro-phenol 10 per cent has invariably proved satisfactory in my hands In ozenatous conditions after freeing the nares from the offensive accumulations, and thoroughly cleansing the nasal mucous membranes with dry absorbent cotton, I have found nothing that will so quickly remove the offensive odor of the disease as two or three applications of 10 per cent ortho-chloro-phenol in glycerin In these cases I persistently but very gently rub the solution over the diseased parts, and the patient is much gratified by the sudden removal of the offensive odor of the disease I have yet to see however a case cured by the application of this or any other drug, that is, having no longer necessity for any applications to the nares In laryngeal conditions I found that it will not in any sense take the place of ichthyol or iodoform as a local application If a caustic effect is required, as for instance upon deeply seated ulcers or upon granulations in the pharynx, it is not to be considered, as its effect is too mild to be taken into consideration In laryngeal diseases the results of persistent application have not lead me to resort to its use excepting in the event of failure of lactic acid, ichthyol or boro-glycerin In three out of fifteen cases of laryngeal tuberculosis in its very incipiency, I have found ortho-chloro-phenol, in full strength, to give better results than any other local application In two instances, most gratifying results were obtained by the application of 10 per cent ortho-chloro-phenol to large ulcers of the epiglottis, both occuring in cases of advanced tuberculosis

For the removal of growths of any sort in the larynx, I would not encourage the use of the drug, as it is not only slow, but also liable to cause acute inflammatory reaction—in one instance, giving rise to very severe dyspnea In aural diseases its use has been attended by more gratifying results than those gained by the use of any other drug The application of a pledget of cotton saturated with the 10 per cent of the glycerol of ortho-chloro-phenol to an incipient furuncle of the external canal, in many instances has resulted in the abortion of the disease, while no dressing has proved more satisfactory after I have been compelled to open the furuncle in the canal Though I have used a dossil of cotton saturated with it as a dressing after opening the furuncle I have never yet seen a recurrence of the disease at a sufficiently early date to warrant me in believing that there had been any material allowed to remain in the ear disinfected A small pledget of cotton saturated with the solution and applied to the point of attachment after removal of polypi of the external canal, has always proved effectual both in destroying the extremely offensive odor, and in encouraging a rapid healing of the parts In suppurative otitis media it has proved exceedingly effectual in 10 per cent in glycerin I will cite but one case as an illustration of many Miss E M, aged 22, applied to me in July, 1893, with chronic suppurative otitis media of the right ear, more than two-thirds of the inferior portion of the membrana tympani had been absorbed The suppuration had continued with more or less severity and an offensive odor, since the early childhood of the patient I employed every method for the relief of the symptoms and checking the disease, even curetting the floor of the middle ear, where the disease seemed to be confined, the attic not appearing to be involved Boro-glycerin in 50 per cent solution, ichthyol, nitrate of silver, zinc, nitrate of sanguinaria, douches, powders as iodoform, aristol, etc, were used without result The discharge continued to be offensive and muco-purulent in character, no matter how thoroughly the application at the previous visit had been made In December, 1894, after having thoroughly cleansed the parts I inserted a pledget of cotton saturated with 10 per cent ortho-chloro phenol in glycerin The patient was instructed to return the following day To my surprise the entire appearance of the parts had changed, the mucous membrane had become more healthy in appearance, and the discharge had lost its odor and golden yellow color In five days and after three applications the discharge entirely ceased, and has not recurred since, excepting in the spring of 1895, when the patient was attacked by an acute rhinitis, and three days afterward complained of discharge from the ear A single application of ortho chloro-phenol caused this to cease after twenty-four hours and there has been no discharge [illegible] uent as a rule complains of consid [illegible] on the first introduction of the [illegible] e drug, but this rapidly subsides and leaves a sense of comfort It has been my custom to dress the ear daily, or not later than every other day, and in no instance of chronic suppurative otitis media have I had any but the most gratifying results in its use In acute suppurative otitis media I have found that in any strength it seems to aggravate the disease The greatest objection raised to the use of the drug comes from the patient, who complains of its odor Even weak solutions of the drug unquestionably give rise to an all-pervading and pungent smell that is more penetrating than that of iodoform This objection, particularly in the application of the drug to the ear, may readily be overcome by closing the external meatus with a small piece of absorbent cotton In conclusion then, I have no hesitation in recommending the further clinic use of ortho-chloro-phenol in the belief that it will prove a valuable addition to the pharmacopeia of the rhinologist and aurist, and prove itself worthy of the fullest confidence, especially in those cases where the commonly resorted to medicaments have not only failed to relieve the patient, but have disappointed the expectations of the surgeon

---

THE ELECTRO-CAUTERY SNARE AS AN EXCISING AGENT IN DISEASES OF THE NOSE AND THROAT

Read in the Section on Laryngology and Otology at the Forty seventh Annual Meeting of the American Medical Association held at *Atlanta, Ga, May 5 8 1896*

BY HANAU W LOEB, A M, M D

Professor of Diseases of the Nose and Throat, Marion Sims College of Medicine, Surgeon to the Nose and Throat Department of the Rebekah Hospital Missouri Pacific Hospital East St Louis Protestant Hospital, Grand Ave Free Dispensary, etc

ST LOUIS, MO

It is only a natural sequence which impels one who has given the electro-cautery snare a trial for the treatment of one of the various conditions for which it is recommended, to extend its application, to find new uses and to confirm those whose work has forced them to admit its growing utility Especially is this to be expected in view of the recent improvements in electric appliances

At the meeting of the American Medical Association at Detroit in 1892, I presented an electric snare which[1] I had devised, and stated its indications and uses in nose and throat diseases Since that time I have, by greater opportunity, enlarged its sphere of usefulness and fixed my own views in favor of a wider range of application of the electro-cautery snare in nose and throat affections From its very nature it is adapted for amputation or excision Any organ or growth or portion thereof which can be engaged within the snare may be removed, without danger of hemorrhage, for not only will there be less hemorrhage than when a knife or cold snare is used, but absolutely no bleeding in the vast majority of cases

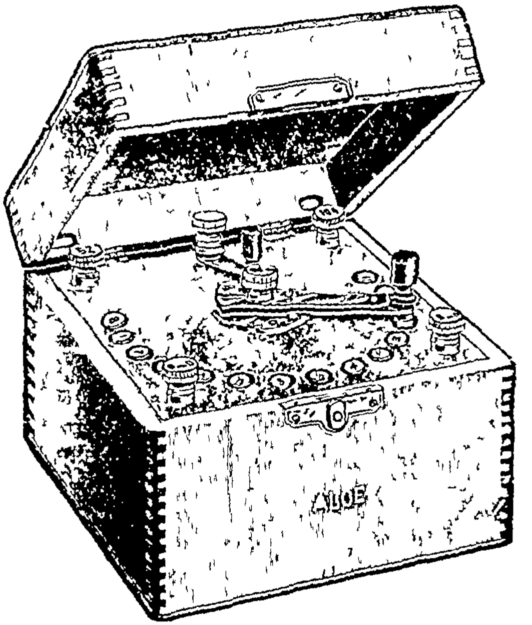
The snare, which was exhibited before this body four years ago, I again present though it is unmodified, except, that in order to accommodate the increasing field of application, it has been made in two sizes By reason of its ready separation, its simple construction and its constituents, it is easily cleaned Being covered with hard rubber it is not open to the objection which the old time snares received on account of their lack of cleanliness

Until over three years ago, I relied upon the ordinary galvanic and storage batteries, without complete satisfaction, constant attention was required to keep them in order and even when the greatest care was observed the battery would often fail at the critical moment

In December, 1892, I began to use the Aloe converter and since that time I have never been subjected to any annoyance on the part of the appliance supplying the current The converter is applicable only to the alternating current and is similar in its design and purpose to the transformers which are now used to reduce electricity of high electro-motive force to a lower tension

The instrument which I have, reduces the voltage from 104 to 1, $1\frac{1}{2}$, 2, 3, 4, 5, 6, 7, or 8 volts, and is therefore suitable for the cautery or the light

In construction, it consists of iron core with a large primary coil of fine wire and a smaller secondary coil The ratio of turns of the wire in the primary and secondary coil will depend upon the transformation required Thus when the voltage of the house current is 104 to secure one volt the primary would have 416 turns to 4 of the secondary, for 2 volts the ratio would be 416 to 8, for 4 volts, 416 to 16, for 8 volts 416 to 32 From $4\frac{1}{2}$ to 6 amperes are required for the proper action of the snare with No 5 piano wire ($\frac{1}{3}$ mm in diameter)



Lichtwitz[2] describes a fairly elaborate instrument which he uses and which he presents as one by means of which the quantity of electricity may be measured He finds that ten amperes are necessary for ordinary tonsils and twelve for the larger, when the wire used is $\frac{1}{3}$ m m in diameter

There are several very good appliances in use for utilizing the constant current which alone is available in some cities

It therefore follows that at the present time no one need deny himself the use of the electro-cautery snare on account of electricity producing apparatus, for, whether the current be alternating or direct the supply will be reliable and precise For some years a valid objection was entertained to the platinum wire on account of its lack of firmness Since iron or steel wire has replaced it however, the same degree of stiffness of the loop is obtained whether the cold or hot snare be used

The electro-cautery snare is from the very nature of things of but recent use So far as I can learn Middledorf was the first to employ it in the removal of tonsils

According to Kijewski and Wroblewski[4] the galvano cautery snare was used by Koehler and Korzeniowski to remove a large polypus which filled the entire nasal cavity Voltolini,[6] in his great treatise upon the galvano cautery considered the value of the snare lessened by reason of the insufficiency and inconstancy of current

Since the publication of this work and especially since the introduction of an apparatus which provides for the regular and certain supply of electricity, this and the somewhat similar objection of Beverly Robinson[7] are answered So satisfactory has been this answer that the advocates of the electro cautery snare have increased immensely, until they include many who are willing to replace by it many operative procedures which legend and practice had almost established forever In fact the most enthusiastic advocates are those who have had most experience with it and its greatest opponents are generally those who have used it infrequently or not at all

Thus Sendziak[8] complains that Jurasz, after employing the electro cautery snare in only two cases, came to the conclusion that it was inconvenient, painful and disagreeable to the patient on account of the odor it leaves

The electro cautery snare has been recommended and employed in the following diseases of the nose and throat

1 Nose *a*, anterior and posterior turbinal hypertrophies *b*, polypi and other benign growths, *c*, malignant neoplasms, *d*, spurs
2 Rhino-pharynx *a*, polypi, *b*, fibromata
3 Pharynx *a*, hypertrophied tonsils *b*, tonsillar neoplasms, *c*, palatal neoplasms, *d*, elongated uvula, *e*, hypertrophied lingual tonsils
4 Larynx *a*, neoplasms

I NOSE

1 *Anterior and posterior turbinal hypertrophies*—In these conditions the electro-cautery snare is almost ideal, permitting the operator to remove quickly the redundant and hypertrophied tissue by means of an operation which is bloodless notwithstanding the great vascularity It is quite as easy to engage the hot as the cold snare and the celerity, the painlessness and freedom from hemorrhage should commend the former over the tedious cold snare

Sajous[9] prefers the electro cautery snare for posterior turbinate hypertrophies, stating that it is necessary to use a rhinoscopic mirror in order to see the seat of operation I consider that this is not only unnecessary, but awkward A far better plan is to place the finger in the rhino-pharynx and thus guide the loop over the hypertrophied tissue

McBride[10] says it should be used whenever the tissue can be engaged and Greville MacDonald[11] prefers the electro-cautery snare for the removal of large pieces of the turbinated in spite of the objection that it induces considerable inflammation in the neighborhood from the generation of steam and that the cicatrization is delayed I can not permit this objection to go unchallenged for at least in my own cases it has not been revealed Among the laryngologists who consider the cold snare as superior for anterior and posterior hypertrophies, may be mentioned Onodi,[12] Zwillinger,[13] Polyak,[14] Eaton,[15] Hack,[16] while Baumgarten[17], Schmidt[18] and others commend the hot snare

2 *Polypi and other benign growths*—The essential advantage of the electro-cautery snare in the removal of polypi is the fact that so many may be removed at one sitting, whereas it requires considerable time to dispose of a number by means of the cold snare, with the hot snare it is only the question of a few minutes The smaller instrument which I have devised is quite as convenient and easy of application as any cold snare, and one needs only inquire of a patient who has had both methods applied, to learn that the hot snare is far more agreeable, less painful, more rapid, less bloody and more preventive of recurrence So far as the inflammatory and infective sequelæ are concerned after a thorough trial of more than four years, I am convinced that they are no greater in one than in the other In one single case, an acute otitis media followed the separation, doubtless influenced by the unwarrantable exposure to which the patient subjected himself The operation was performed in the morning and before night the patient had permitted himself to be drenched by rain several times He failed to report at my office until the fourth day after the operation I feel therefore that the hot snare may be held blameless of this result Surely the lessened time of operation should make infection less apt to occur than with the cold snare with which too often no aseptic and antiseptic precautions are taken

McBride[10] in this connection makes the assertion that it is better to use the electro cautery snare, when it is desired to remove all the polypi at one sitting Ingals[19] uses the electro cautery snare but prefers the cold while Greville MacDonald[11] claims that there is no advantage over the cold snare, while there is the greater disadvantage of inflammatory action induced by heat and steam generated by the hot wire

In answer to this, it may be stated that the heat and steam which MacDonald and others claim are generated will not produce any bad results if the snare is properly applied and used If the wire is drawn tight the tissue which is influenced by the heat will be so constricted and the time of its application so insignificant, that it can have but little influence in this regard It is often difficult, sometimes impossible, to observe the cauterized stump, demonstrating that at least in many cases the effect of the heat and steam is *nil*

Schmidt[18] states that after using the cold snare for three years he returned to the electro-cautery This, I am sure, will be done by many if they give the latter a fair trial I am inclined to agree with Ball[0] and others that cauterization of the base resulting from the galvano cautery ablation of polypi is productive of good results In keeping with the progress of rhinology, I do not believe that mere cauterization of the base will prevent recurrence Indeed my common practice now is to remove all larger polypi with the hot snare, and if the bone is found affected the smaller polypi with the diseased bone are then removed

The electro cautery snare is also available for the removal of other benign growths in the nose, and I have used it with good effect in fibroma, adenoma and papilloma In one case of fibroma, which projected from the rhino-pharynx, the vascularity was very great, the growth bleeding upon the slightest provocation yet, the electro-cautery snare caused the loss of but a few drops of blood In the case of adenoma I first used this instrument but in the later recurrences abandoned it, since on account of the softness of the tissue and slight amount of blood which was lost, I could operate quite as well with forceps

Zarniko[21] inclines to the cold snare for removal of inflammatory fibroma, claiming that if it is applied as he suggests, the loss of blood will be inconsiderable

3 *Malignant tumors*—The electro-cautery snare has in this class but a limited range, which is in the direction of securing a portion of the growth for microscopic examination

4 *Spurs*—Although advocated by a number of laryngologists, I have never taken kindly to this form of treatment The saw, drill and curette are eminently more satisfactory The electro-cautery snare is by no means as free from objection in operations upon bone and cartilage as upon softer tissues

II RHINO-PHARYNX

1 *Polypi and fibromata*—These may well be considered together as the terms are used interchangeably by many In appropriate cases the belief seems to be fairly general that the hot snare is of greatest service, although the electrolytic treatment seems destined to overshadow all other forms, except where a more serious operation is indicated However, many still maintain the superior value of snaring where this is possible Thus Michelson[22], Lincoln[23], and Schmidt[20] report cases of rhino-pharyngeal fibroma treated in this way I have used the electro-cautery snare in two cases of rhino-pharyngeal polypi with success and without return In a case of rhino-pharyngeal fibroma with projections into the nasal cavity I snared off as much as was possible to reach with the instrument On the whole the efficiency of the electro-cautery snare in rhino-pharyngeal tumors depends upon the possibility of engaging the growth in the loop and its extent and attachment

III PHARYNX

1 *Hypertrophied tonsils*—In the removal of hypertrophied tonsils, the electro-cautery snare has received greater attention than in any other affection After this method was introduced, according to Lichtwitz[2] the operation lost caste but was revived through the writings of Knight, Loeb, Garel, Schmidt, Heryng and Sendziak All of these continue to favor the electro-cautery snare except Knight, who writes[24], after a complete resumé upon the subject of hemorrhage following tonsillotomy that he favors the guillotine

Flatau[25] intimates that those who have experienced serious hemorrhage after tonsillotomy are much inclined to replace the tonsillotome with the electro-cautery or electro-cautery snare and McBride[10] states that its use is only justifiable in preventing hemorrhage, which he states is a rare contingency Bresgen[26] dismisses its consideration with the remark that there *is no reason* for its use as it does not prevent hemorrhage Bosworth[27] objects to the procedure on the ground that it requires ten to fifteen minutes and Potter[28] advised that the snare be not adjusted too deeply on account of the sloughing beyond the seat of cauterization

Ingals[19] favors the cold snare On the other hand there is a great array of experienced advocates of electro-cautery tonsillotomy Lichwitz[2] is strong in his preference Yerwant[29] states that it is more prudent to use the electro-cautery snare in adults so as to obviate hemorrhage Heryng[30] has given his evidence in its favor for hard fibrous tonsils, extensive hypertrophy and hemophilia Sendziak[18] advocates it forcibly and conclusively, stating that any one without prejudice will be *entirely satisfied* with this method Schmidt[18] favors the electro-cautery snare beyond all other tonsillotomy instruments He denies that it requires a longer time than the operation with the tonsillotome and insists that it is to be preferred on account of the certainty that hemorrhage will not occur Huguenin[31] advises the use of the electro-cautery snare whenever tonsils are pedunculated and Helot[3] also prefers this instrument There is to my mind no question as to the safety of galvano cautery tonsillotomy so far as hemorrhage is concerned A few cases of hemorrhage following this operation have been reported, but never a serious one They could all probably be explained upon a satisfactory basis In more than 300 tonsillotomies with the electro-cautery snare I have nerver observed a loss of more than a few drops of blood In only one case was there a secondary hemorrhage, which doubtless resulted from a lack of attention on the part of the patient I think this will compare favorably with the experience of those who use the knife or tonsillotome In fact the proof is stronger when it is considered that the hemorrhage would be far greater if the advocates of the knife would remove as much as is ordinarily removed with the galvano cautery snare

Numerous instances of hemorrhage after tonsillotomy attest to the possible seriousness of such an occurrence Heryng[30] collected fifty-nine cases of severe and even serious hemorrhage, other cases have been reported by Blairs,[33] Fuller,[34] Catuffe,[35] Moure,[36] Thorner,[3] Jessop[38], and Lennox Browne[39]

Another great advantage which the galvano-cautery snare possesses over the tonsillotome consists in the large amount of tonsillar tissue which it is possible to remove and the precision of the operation which makes it possible to remove just what one desires With the tonsillotome the amount of tonsil removed is purely accidental If the instrument possesses a fork or lifting device, the amount will depend upon the pulling power of the fork, which to the surgeon can not be known until after the excision If there is no fork, the pillars of the palate will limit the removal, and therefore it must be very exceptional to remove the entire tonsil Quite different is it with the electro-cautery snare It is my custom to pull the tonsil from its palatal bed by means of a pair of sharp-toothed forceps and then engage the wire so that it is possible to remove the entire tonsil I have again and again made so complete an excision that not a vestige of tonsil tissue remained This I do not consider a dangerous practice, at least it has been eminently satisfactory up to the present time I can corroborate the experience of Schmidt,[18] who states that he has frequently seen enlarged tonsils of which one-fifth only had been removed by previous tonsillotomy

As to the great length of time which some writers maintain is necessary in operating with electro-cautery snare, the expression is born of inexperience, for no one who undertakes it a number of times can fail to acquire sufficient dexterity to operate with celerity It never should require more than one minute, providing the apparatus is in proper working order, considering the improvements that have been made, nothing short of this is to be anticipated On the whole it must be admitted that the electro-cautery snare is to be commended for the removal of hypertrophied tonsils in that it obviates all danger from hemorrhage and makes the operation one of precision, not one of the purest guess-work

Even in tonsils which are impacted between the palatal pillars it will be found of service, since in almost every case it will be possible to pull out a portion and engage it in the snare, thereby not only securing the advantage of cauterization, but also the removal of a portion of the hypertrophied tissue

2 *Tonsillar neoplasms* —Any tonsillar growth which has not involved and attached itself to neighboring structures is susceptible of excision with the electro-cautery snare This does not imply that the mere removal with the snare will constitute a cure for such an affection However, if the growth involves the tonsil alone, and the entire tonsil is removed, the method should offer at least as good a result as any other In a case of lymphosarcoma of the tonsil I snared off a large piece of the tumor for microscopic examination, without causing any hemorrhage and without influencing the growth of the tumor Wolfenden[40] states that he removed a sarcomatous tonsil by means of the electric snare, and I consider it a procedure which should be utilized in the earlier cases

3 *Palatal neoplasms* —Tumors of the palate which may be engaged within the loop are suitable for removal with electro-cautery snare I have used it twice for palatal papillomata

4 *Elongated uvula* —In my previous paper[1] I called attention to removal of elongated uvula by means of the electro-cautery snare, which I had practiced for some time Shortly after this DeBlois[41] in a paper before the American Laryngological Association, took a similar position Lennox-Browne[42] states his preference for the galvano-cautery where the uvula is thin, but he does not specify the snare He operates by pulling the uvula downward and cutting it with the galvano-cautery where he desires On the other hand Morgan[43] and Ingals[19] prefer the cold snare That hemorrhage is a possibility, one needs only to refer to the paper upon this subject written by Morgan[44] in which attention is called to a great number of instances of uvular hemorrhage collected from ancient and modern medical literature

Besides entirely preventing all possibility of hemorrhage the hot snare operation finds an indication in the ease with which the uvula can be engaged, the perfect stump which remains, the smaller amount of pain succeeding the operation as compared with ordinary uvulotomy It is my practice after the uvula has been properly cocainized to permit it to fall into the loop and after deciding exactly where the section is to be made, to draw the wire tight and send the current through So pleasing are the results from this method of operating, that I now use no other plan

5 *Hypertrophied lingual tonsil* —My own experience in this particular affection is confined to one case, however, it seems to offer an inviting field at least Sendziak[8] commends it highly

IV LARYNX

1 *Neoplasms* — Some writers are disposed to favor the electro-cautery snare in these affections, but it seems to me that there are serious objections on the score of inaccessibility, impossibility of keeping the site in perfect view, the danger of inflammatory reaction and the possibility of the excised tumor falling into the larynx These are, however, the judgment of opinion rather than of experience

In conclusion I desire to state that the electro-cautery snare has a possible indication in laryngeal tumors and nasal spurs, an inviting one in hypertrophied lingual tonsils, palatal, tonsillar and rhinopharyngeal growths and a certain one in the removal of hypertrophied tonsils and turbinates, nasal polypi and elongated uvula

DISCUSSION

Dr W E Casselberry, Chicago Ill —I think the success of treatment by the electro cautery snare depends very largely upon the perfection of one's apparatus I think that Dr Loeb deserves a great deal of credit for having designed an apparatus by which he can *gauge and perform* these *operations* with facility He is fortunate in having his converter and an alternating current I have been unable to find a satisfactory galvano cautery rheostat by which to use directly the Edison or continuous current, so I use the storage battery I use for this *purpose* the double American cell, keeping it stored constantly by the Edison current in connection with my light so that the flow of the current from the battery seems to be uniform I am not accustomed to take out nasal polypi with the cautery snare I formerly did it but have stopped *for* the reason that it makes the nose sore I can remove about as many as I care to at one sitting with the cold snare I remove tonsils in adults sometimes by the cautery snare It has the advantage of avoidance of hemorrhage *and the* disadvantage of making a very sore throat I think, to remove the uvula by the cautery snare, I must make a more painful wound than by the usual method

Dr Hanau W Loeb, St Louis, Mo —**I expected** to h more criticisms than have been made and would have been deserved, for I am sure that my love for the electro cautery snare has made me rather dogmatic I use a better instrument than those usually employed Most of the instruments have too large a handle and are too heavy, but I have somewhere in the gray matter of my brain a little handle in view which will greatly obviate this trouble

I think Dr Casselberry deserves a great deal of credit for his faithful work with that abominable machine, the winding cautery snare I use the McIntosh handle, which has a sliding arrangement by which the loop is tightened in a moment

It is unfortunate that in so many cities the direct current is still used Since the consolidation, however, of the Edison and Thompson companies, they are not using them so much, and soon the alternating current will be utilized in all of the larger cities In reference to trouble from cauterizating the adjoining part, if the wire is drawn tight before sending the current through this will be obviated The trouble with the instruments is that you have to pass the wire through the cannula and then back again In mine there are two perforated wires which are threaded like a Sajous snare

There is no question but that in many cases the inflammatory reaction from the electro cautery is greater than the cold snare, for the reason that the surface is free from all germs; since I have become more familiar with the use of the instrument I have severe inflammatory results less frequently It is the best in operating upon the uvula because one is not required to pull down the tip in any way I simply let the uvula fall into the tip and turn on the current In the scissors operation you are apt to cut off more than is necessary of the mucous membrane, and in addition the inflammatory results are greater I have presented this paper because there is a scantiness of literature in regard to the cautery snare for operations in the nose and throat I hope that when we next speak on the subject, I will have more in favor of it

ON BONY GROWTHS INVADING THE TONSIL

Read in the Section on Laryngology and Otology at the Forty seventh Annual Meeting of the American Medical Association, at Atlanta Ga May 5 8 1896

BY ALEX W STIRLING, M B, C M (EDIN), D P H (LOND)
ATLANTA GA

The cases which I bring before you are interesting, I think, from the points of view of both the anatomist and the practical surgeon

The first is that of a young lady of excellent personal medical history Her only complaint had been slight chronic hypertrophic rhinitis, and for a few years some enlargement of the tonsils, especially the right, both of which secreted caseous matter and were at times a little painful The inferior turbinated bones and the varicose veins of the lingual tonsil had been cauterized by one throat specialist, another had cauterized her right tonsil, and a third had cauterized cysts in both

When tired she frequently complained of pain which she believed originated in the right tonsil and radiated thence to the mastoid and the right nasal bones, as well as to the right eye and shoulder When squeezing out secretion she could feel a local tenderness in this tonsil

On examination with the finger I was able to make out a hard immovable mass coming from behind the tonsil forward underneath it to the level of its anterior surface, but forming practically part of its substance Its point is rounded, apparently about one-eighth of an inch in diameter, but becoming broader and somewhat flattened laterally as it extends outward, backward, and slightly upward The finger pressed in front enters an angle formed by it and the inferior maxilla, and when pressed behind it enters another angle formed by its approximation to the right side of the vertebral column The tenderness felt on pressure appears to be due to the nipping of the tonsillar mucous membrane between the finger and the hard body *Nothing of the kind can be discovered on the left side*

The second case consulted me on account of large polypi of both nostrils from which she had suffered for years She is 64 years of age, has asthma and a weak cardiac muscle, but otherwise is in good health There is nothing of note in her family or personal medical history On examining her throat I observed a slight protuberance just above and in front of her right tonsil With the finger I found it to be nearly the same as that described in connection with Case 1, with the following points of difference In the second case it exists on both sides, though it is not quite so prominent upon the left side, it is also higher, farther forward, perhaps a little thinner, and with a more apparent upward direction

The growth is quite immovable, and there is no unnatural tenderness on examination The patient has never had the slightest trouble with her tonsils I have been able to examine the throat of one of her daughters, but could find nothing unusual there

The third case is a brother of Case 2, aged 65 He likewise has been free from throat affections or any infirmity which might have a bearing on this subject On both sides he has the same peculiarity, but differing from the previous cases in that the hard masses are altogether in the posterior part of the tonsils, are much longer, reaching a full finger breadth below the level of the lower tonsillar border, are perhaps rather more slender and, for nearly half an inch of the lower end on either side, cartilaginous to the touch and movable

The question now arises, what are these substances? They are evidently not tonsillar calculi, because they have none of their characteristics except tenderness In view of the fact that they have given rise to no symptoms whatever in two cases, and from their formation, position, and immobility, it seems to me certain that they are not the result of disease, but that they are rather congenital peculiarities, having however a distinct interest in cases of disease in their neighborhood

In endeavoring to come to a decision relative to their origin, let us examine the bony structures from which they might arise, for they can be nothing else than bone They all arise on the outer side of the throat, and it may be from the lower jaw, the vertebral column, or the base of the skull If they came from the lower jaw to which they closely approximate, they would move along with it, but not one of them does so They do not come from the bodies of the vertebræ, because the finger can exclude these The pterygoid plates are too far forward, the spines on the posterior extremities of the wings of the sphenoids are rather less unlikely, but they too are somewhat too far forward and are distant It is much more likely that the growths are simply prolongations of natural prominences than entirely new formations, by a process of exclusion we are limited to the transverse processes of the vertebræ and the styloid process

The tonsil is situated on the level of the upper part of the body of the axis or of the disc between it and the atlas The transverse process of the axis is small and does not move on rotation of the head The bones under consideration do move along with the head on rotation, and come into much greater and visible prominence when the head is turned toward the side opposite to that under examination

We are therefore reduced to the atlas which is as regards rotation of the head a part of it and the styloid process To which of these the bones belong is a question of interest chiefly in view of the possibility of their becoming carious or involved in an operation, for disease affecting the styloid process might spread to the main body of the temporal bone, and the delicate structures in relation with it, and if the atlas were in any way injured at least a serious condition of things might arise

Upon this atlas, kindly lent to me by Dr Grandy, with this skull, the posterior limb of the transverse process which ought to, but does not, join with the anterior to complete a foramen, is nearly an inch in length, and were it longer would reach the region of the tonsil if its curve were continued, or were a little accentuated and its direction would correspond fairly well with that of the growth especially of the first case

The direction and size of these growths afford no satisfactory point for differentiation Neither does the movement of rotation, and the only way to distinguish between them, of which I have been able to think, is that the skull proper moves when the head is nodded which is not the case with the Atlas These bones move with the head on nodding, and I therefore conclude that they are styloid processes Other arguments in favor of this view are the presence of cartilaginous terminations in the case of the male patient, and the well-known variability in length of the styloid processes I have been able to obtain little or no assistance from literature in making my diagnosis Among the books on anatomy and diseases of the throat which I have been able to consult, I have found only one reference to such a condition as this A few cases of exostosis of the bodies of the vertebræ, having no resemblance to these, have been recorded Three widely-known specialists on throat diseases with whom I have been in correspondence, and one of the most experienced of European anatomists have all informed me that they have never seen such a condition as I described to them

The one reference to any such which I have seen is in Schech's book on diseases of the mouth, throat and nose He refers to a case "described from the anatomic point of view by W Gruber," and another from a clinical aspect by Lücke, while Weinlechner is said to have broken away a piece of bone which caused inconvenience in swallowing These are recorded as abnormally long styloid processes

This condition of the tonsil is not to be looked upon as a mere anatomic curiosity, for in two at least of my three cases an attempt at tonsillotomy might have been met with considerable difficulty had a correct diagnosis not been previously made, and it might be of consequence in other operations in that region As regards treatment, there is no necessity to interfere in the cases of the elderly people The tonsils are troublesome in the first case, and it is a question whether removal of part by the guillotine, cautery or otherwise, or even the breaking up of it with a blunt hook might not result in so tightly stretching the mucous membrane over the bone as to produce pain or even ulceration and exposure of the osseous tissue Personally, unless in case of urgent necessity, I should be averse to removal of the latter on account of possible secondary mischief in the bone, or of interference with the attachments of muscles and ligaments

DISCUSSION

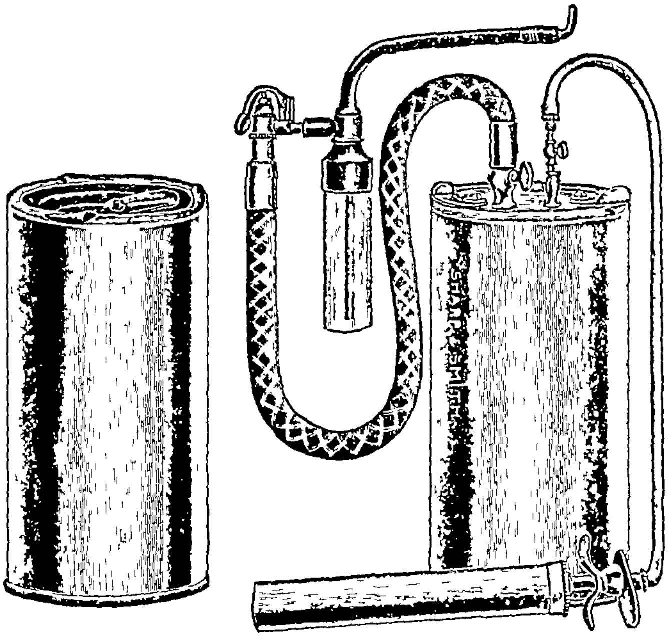
Dr W E Casselberry, Chicago, Ill —I saw these very interesting cases The first case to which he has reference, is a very distinct pointed prominence on the right side occupying the location of the anterior pillar, which covers it more than the tonsil, although when it is stretched forward the tonsil will cover it The curvature inward and the position would satisfy me that it was a styloid process turned inward toward the throat The other case had much the same condition but is not so pronounced The committee agreed that the case was an abnormal styloid process It is of some importance in connection with possible operations on the tonsils In regard to operating, laryngologists should take palpation more into consideration Upon palpation they would discover that there was something of a hard nature and would be warned against operating I do not think anything serious would occur if an operation was attempted, I think the instrument in both cases would slide over the projecting point rather than go through it I would not make a tonsillotomy in that case or cauterize it, because the somewhat enlarged tonsil affords a useful padding to the short pointed projecting styloid process

---

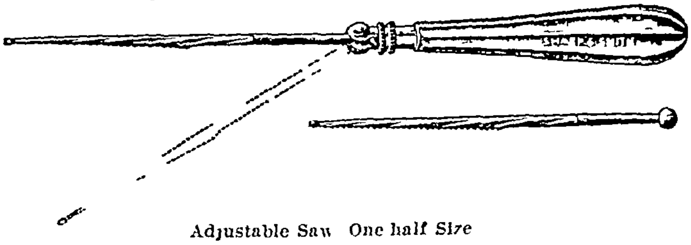
PORTABLE COMPRESSED AIR APPARATUS AND NASAL SAW

Presented to the Section on Laryngology and Otology at the Forty seventh Annual Meeting of the American Medical Association, at Atlanta Ga May 5-8 1896

Dr E Fletcher Ingals, Chicago, Ill , presented a portable compressed air apparatus, with the following remarks This is a compressed air apparatus designed for treating patients where we are obliged to carry an apparatus with us, as for instance in going to theaters to treat actors, or for the use of patients who need a high air pressure for making applications to the larynx or Eustachian tubes It consists of a cylinder eight inches in length and three and a half inches in diameter, capable of withstanding eighty pounds pressure The cylinder has a movable head that will slide in so that the spray tube, pump and all other parts of the apparatus may be placed inside the cylinder when not in use To use it the [illegible] up against a rim with a rubber washer [illegible] by clamps that make it air tight. The [illegible]



Portable Air Compressor, One quarter Size



Adjustable Saw One half Size

feet in length, so that the patient can hold the cylinder in the lap while the application is being made A bicycle pump is employed, which is of convenient size to go inside the cylinder when packed, but is of sufficient size to enable one to easily obtain forty pounds pressure The cylinder filled with compressed air by this means holds sufficient to throw a strong spray the length of time necessary for treating five or six patients

The price of this first apparatus, without a case was $15, but as more are made the manufacturers say they can be furnished in a leather case with space for a reflector, throat mirrors and extra solutions, if desired, for $15 The case complete with the extra space for other instruments will measure only eight and one half inches in length, four inches in width and five inches in height, or without space for head mirror will measure eight and one half inches in length, four inches in width and four inches in height

Dr Ingals also presented a nasal saw with an adjustable handle that could be set at any angle The instrument was provided with two blades, one to cut forward the other backward It had proved very satisfactory It was made entirely of metal

---

HYSTERIC DEAFNESS

Read by title in the Section on Laryngology and Otology, at the Forty
seventh Annual Meeting of the American Medical Association

That protean affection, hysteria, may be considered a purely functional disease There is, however, usually some concomitant affection or lesion which may be deemed to be the cause This may excite a local hysteric attack in a patient predisposed by mental or moral influences Some actual injury or shock to the part is in many cases the predisposing cause for the local manifestation Affections of the sight are frequently seen, indeed, in most hysteric persons it is possible to find some defect of the visual field

Hysteric deafness is very rare In the *Medical News*, Feb 14, 1891 I reported such a case Since that time two more have come to my notice

Case 1 —Hysteric deafness and blindness in a woman after injury to the head

Aug 29, 1892, a woman, age 42, was sent to me on account of monaural deafness She gave a history of a railroad accident a few days before in which she had been struck on the left side of the head, had been prostrated and in bed after arrival in this city She claimed to have had severe pain in the left ear the day before and discovered that this was totally deaf

Status Presens Patient very nervous and excited There was a contusion with swelling over the left orbit and malar bone of same side, which patient thought was broken, but examination showed no evidence of fracture The vision of this eye was slightly reduced for distance and she claimed that she was not able to read ordinary print Objective examination of the eyes was negative, the refraction and fundus normal, pupillary reaction and pupils normal Contraction of the visual field on the affected side Examination of the ear showed a normal drumhead and no visible cause for the pain or deafness She could only hear loud sounds on this side That of the right was normal Tuning fork placed on vertex was heard only on the right side and not at all on the left by aerial or bone conduction There was no tinnitus or aural vertigo at this time Two days later the left ear appeared totally deaf She complained of great pain in the back and leg of this side and of hypresthesia She asserted that the whole of this side was weaker than the other Objective examination showed left hemihyperesthesia and a questionable hemiplegia Treatment advised was absolute mental and bodily rest with bromid of kalium and valerian Diagnosis at the time was hysteric deafness the locality of the functional disturbance being probably influenced by the character and place of the contusions A prognosis was given of probable recovery either after the effect of the primary shock had passed away or after the lapse of some weeks

One month later I examined her again, finding that she could hear a loud voice but could not understand spoken words on the left side, hearing on right side normal as on first examination Objective examination negative Tuning fork only heard on the right when placed on the vertex She was excitable and had an anxious countenance and complained of pain in the back of the head with creepy sensations and weakness on the left side of the body Also had pain in the ear and roaring sounds which were immediately relieved by weak galvanic electricity Patient had a fainting fit in the street car on returning home from my office The vision was blurred for reading in both eyes in a few minutes There was now no contraction of the visual fields and the vision was normal for distance About three months later the railroad company having settled with a moderate sum for damages, the hearing gradually came back to the affected side, and examination one year later showed that it was normal

Case 2 —Hysteric deafness and blindness in a child after pulling the ear

Nov 9, 1893, an anemic child, aged 11, had trouble at school several weeks before when the teacher pulled her right ear She became totally deaf on that side and partially so in the left within a few hours, complained of her sight and was light shy Was given near sighted glasses (—1 D) by a jeweler, with which she claimed she could see better, and without which she kept her eyes closed

Status Presens The child was apparently apathetic and stolid The right concha was red and exquisitely tender to the touch caused, as I observed, by furtively pulling the ear when she thought she was not being watched The membrana tympani were normal She has slight hypertrophic rhinitis for which the mother had been douching the nose with a syringe and salt water Patient could not understand what her mother said, although she had been shouted to for a couple of weeks, but she was apparently observant of our conversation On taking the child aside I found that she understood me when I talked in an ordinary tone of voice All tests for hearing were useless

Her vision was R and L 6-18 with her glasses and without them she would not read any letters I explained the case to the mother and commenced at once to make a decided mental impression upon the child, *i e*, to hypnotize her I told the mother in the child's presence, in a manner to give her the impression that I did not wish the patient to hear what I said, "that I was about to do an operation that would cure her at once" The child seemed apathetic but responded to the usual *hypnotic suggestions and on brisk Politzerization* with chloroform vapor, could immediately hear ordinary conversation, her mother's voice as well as mine Hearing tests showed that she could hear the acumeter, the watch, whisper, voice and tuning fork at a normal distance and in a normal manner, besides this she could read all the test letters to 6-VI without glasses These were taken away from her, but a subsequent examination showed that the eyes were 1 D hyperopic The child would not allow of a second Politzerization without hypnotic influence, but the effect of the one given was sufficient to cure the case Tonic treatment was instituted, and as long as the case was under observation (six months) no return of the hysteric symptoms recurred

I can not ascribe either of these cases to malingering entirely, although in many cases of traumatic hysteria there is a tendency toward deception It is probable that the disturbances of special sense in both cases were entirely beyond personal control and were only to be cured by outside suggestion The first case would not submit to such treatment, but in the second it was thoroughly successful I have seen other cases of hysteria relieved in quite as remarkable a manner

805 Grand Avenue

Amblyopia Consequent to Chronic Endometritis —Monte Mor describes in *O Brazil Medico*, August 1, a case of almost total blindness accompanying chronic uterine disturbances Dilatation and curettement with antiseptic injections, etc , cured the endometritis in fifteen days, and with it the amblyopia He queries whether the visual trouble could have been of hysteric origin, but adds that the duration, over a year, argues against this supposition

HE ANATOMIC CHANGES IN TWO CASES OF RETINAL DETACHMENT

ad in the Section on Ophthalmology at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5 8 1896

BY ROBERT L RANDOLPH, M D
BALTIMORE MD

I have selected these two cases as being fairly pical of the two principal conditions leading to tinal detachment first, a spontaneous detachment e to fibrillary degeneration of the vitreous body, d the second case was one where a small round cell coma had lead to propulsion of the retina away om the choroid

In case one the detached retina as it sprang from papilla appeared like a funnel having a neck about e-fifth of an inch long and which at this distance m the papilla commenced to assume the funnel-e shape The retina was detached below, all the y around to the ora serrata Above at a point one-teenth of an inch posterior to the ciliary muscle it s lying *in position From this point it turned* kward and then passed directly down to a point ich lay *in the pole of the lens, and from here took* ourse forward and then upward and finally lost lf in the ora serrata *That part of the funnel* ch had an upward direction was thrown into nerous and intricate folds and enclosed in its hes a mass of vitreous body while that part which sed below was composed of the entire thickness of retina which appeared quite normal The peculi-y of this portion was the absence of folds The er surface of the retina at the widest part of the nel was covered with a thick mass of vitreous body the angle which was formed by the ciliary body ront and by the retina behind, as it fell backward downward from the ora serrata, was filled with gulated material and fine fibrillæ, which latter ed forward and served to form numerous bridges ss this angle The ciliary processes were covered eriorly with several layers of the vitreous fibrillæ zonula was not distinguishable as such, it no ot being merged into the vitreous fibrillæ That ion of the vitreous lying between the retina and oid was empty No doubt we had a fluid here ng life At some points anteriorly could be seen are described by Nordenson as the choroidal , which appeared like little bridges uniting the a and choroid There was nothing worthy of about the choroid and the same could be said of iliary body, iris and lens There was a great tity of material in the interior chamber which probably transudate, coagulated by the hard-g process

croscopic Changes —The changes in the retina very noticeable and particularly in the anterior of the eye The anterior portion of the detached was the seat of the most marked degenerative ges the retina itself resembling closely a reticu-tissue in which there was hardly a trace of the al layers Posteriorly it was easy to recognize everal layers but they gradually disappeared d the ora serrata and the only evidence of a was a single row of granules which marked the e of the external granular layer The layer of nd cones was intact in several places but this tion was usually found in the posterior half of e At those points where the retina was thrown ery intricate folds this layer was more apt to be absent, but even in this situation it was sometimes present In those situations where the layer of rods and cones was absent its place was filled by a mass of albuminous drops, which were arranged in layers one on top of the other On the inner surface of the retina one could see the meshes of the vitreous fibrillæ, which appeared to be exercising traction upon the surrounding retina This layer of fibrillæ was tolerably rich in nuclei In one place the retina had curved around so as to form a loop, on one side of this loop all the layers were to be seen with the exception of the ganglion cell layer The layer of rods and cones could be plainly seen as well as the external limiting membrane On the opposite side of this loop the only layers which were present were the external granular and the external molecular, the latter to a very limited extent The inner layers in this situation had been pulled out of all shape by the vitreous fibrillæ The external granular layer presented generally a very irregular border line appearing at points as papilla-like projections, due I think to the folding of the retina The layer which occupied the usual position of the nerve fiber layer and which to a large extent was that layer, was the seat of numerous nuclei The radiating fibers of Müller showed generally a wavy course The line of demarcation between the ganglion cell layer and the nerve fiber layer was difficult to make out This was no doubt to be attributed to the traction exerted upon the nerve fiber layer by the fibrillæ and also by the very irregular course followed by the radiating fibers As a rule the ganglion cells had dropped out of the section and it was impossible to identify this layer An examination of the neck of the detachment, or as I have called it, the neck of the funnel, showed no remains of the vitreous body

This neck appeared to be a mass of connective tissue in which it was impossible to distinguish any of the retinal layers though it seemed to be made up largely of the granular At the papilla there was no semblance of the retinal structure There was too at this latter point a notable absence of blood vessels Upon the neck of the detachment on all sides there were resting several layers of albuminous drops The fibrillæ were for the most part devoid of nuclei They often appeared as though they came directly out of the retina and made their way into the vitreous body or as though they were prolongations of the radiating fibers, so intimate was their connection with the latter

Choroid —On the inner surface there were several layers of albuminous transudate resting on the pigmentary layer of the retina, which layer had remained behind as it usually does in such cases Increased nucleation was everywhere present throughout the choroid, and further than the points just mentioned, there was nothing noteworthy in this part of the eye The vitreous body was entirely wanting in the posterior part of the eye Just behind the lens it seemed to be transformed into granular debris devoid of fibrillæ, while in other portions it was composed apparently of the fibrillæ which have been described The lens, iris and ciliary muscle were normal

The chief points then about the pathologic anatomy of this case were 1 The widespread atrophic degeneration of the retinal layers and especially of the layer of rods and cones As a general thing the granular layers were the only ones which were preserved 2 Swelling of Müller s fibers 3 The prese of albuminous drops in various localities, especially between the choroid and retina and along the neck of the detachment, and finally the transformation of the vitreous body into the fibrillæ

The second case was that of a boy aged 7 years who came to the Johns Hopkins Hospital early this spring His parents had taken him to an oculist several months previously and at that time his eye was not thought to be in a serious condition He had been complaining for the last three weeks of severe pain in his right eye and his parents had noticed a whitish yellow reflex from this eye This was very noticeable when he came to the hospital The tension of the eye was decidedly elevated and the conjunctiva was injected Vision in this eye was completely gone I advised enucleation and the eye was removed the following day The macroscopic condition was as follows The tumor involved almost the entire nasal half of the retina, filling up that side of vitreous space both above and below It extended backward and seemed to proceed from the nasal side of the optic nerve and, advancing into the vitreous, stopped at a point about a quarter of an inch posterior to the lens Over the area occupied by the tumor there was no trace of the retina to be seen On its free side the growth was quite nodular and one of the nodules projected across to the temporal side of the eye and almost reached the retina on that side The retina in the temporal side of the eye was completely detached

Microscopic changes The tumor was scant in intercellular substance and was made up of small round cells Blood vessels were quite numerous and they were usually filled with red blood corpuscles Large areas of the growth failed to take on the hematoxolin stain but stained with eosin These were evidently necrotic areas Hemorrhages were frequently seen Wherever the tumor was present the retina was indistinguishable, the tumor having grown into it The tumor cells were found in the optic nerve as far back as a quarter of an inch from the papilla The vitreous body had been crowded over to the temporal side of the eye and transformed into the characteristic fibrillæ, which were exerting traction upon the retina and had pulled it into intricate folds in the anterior portion of the eye and just behind the lens the traction was enough to pull the retina backward to such an extent that there was only a short, narrow bridge separating the latter from the growth The layer of rods and cones was nowhere visible, and as in the first case, the ganglion cells had dropped out of the section The internal and external granular layers were clearly definable from the equator around to the ora serrata The retina posterior to the equator was very much thickened and broken down, failing to stain At one point only, and for a very short distance, the external limiting membrane could be seen The fibers of Muller were somewhat swollen and had a wavy course, which more or less disturbed the position of the retinal layers The choroid nearly everywhere had been attacked by the growth, large and small heaps of sarcoma cells were present in this coat and generally they were resting under the pigmentary layer of the retina, which latter was pushed up This condition extended around as far as the ciliary region on the nasal side and on the temporal side a short distance from the papilla There were no albuminous drops The principal changes in this case were the conversion of the vitreous body into fibrillæ and the atrophic degeneration of the retina in the anterior part of the eye

It would seem then that fibrillary degeneration of the vitreous body is to be found in both classes of cases In the case of spontaneous detachment it was evident that the fibrillæ were largely concerned in pulling away the retina from its normal position and from the arrangement of the retinal folds shrinkage or contraction from within must have been going on In this case there was a considerable exudate consisting of albuminous drops resting on the membrana limitans externa, which exudate no doubt played a part in separating the retina and choroid These two conditions would explain the detachment in the first case and similar ones In the second, the presence of the sarcoma was sufficient to lift the retina from its position, though even here it was clear that the retina was subject to a force from within which helped to pull it still further away from the choroid I failed to discover a rent in the retina in either case

In conclusion, then, the most striking anatomic change in these two cases was the fibrillary degeneration of the vitreous body, a condition which I think is found more or less in every case of retinal detachment, and which probably is the chief element in the pathogenesis of the disease

ETIOLOGIC FACTORS, OTHER THAN MYOPIA, IN THE PRODUCTION OF RETINAL DETACHMENT

Read in the Section on Ophthalmology, at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga May 5-8 1896

BY H O REIK, M D
Assistant Surgeon Baltimore Eye, Ear and Throat Charity Hospital and Assistant in Ophthalmology and Otology Johns Hopkins Hospital
BALTIMORE MD

Of all cases of retinal detachment, between 40 and 50 per cent occur as the result of high degrees of myopia with the severe choroido-retinal changes that attend this refractive condition In most of these cases the separation occurs spontaneously, but even in those in which it is the direct or immediate result of traumatism the eye has been previously prepared for this accident by the weakening of its tissues In a study of the other 50 or 60 per cent we are compelled to attribute their origin to quite a variety of causes

The first of these to consider, because of its frequency, is trauma Whether the eye be myopic or hypermetropic, diseased or healthy, a wound and particularly one that penetrates the sclerotic and choroidal coats, may give rise to intraocular changes that result in disorganization and separation of the choroid and retina A myopic eye, or one that is the subject of choroidal or retinal disease, is predisposed to detachment, and in such cases often a very slight blow will produce very serious consequences Any severe blow, or injury about the head, may produce detachment, and Dr Maher has reported a case which he believes, and with apparently good reason, to have been caused by the use of forceps at birth

The next largest number of cases are the result of pathologic conditions of the choroid or retina produced by those diseases of the kidneys which may be grouped under the general title of albuminuria It is not uncommon to find associated with Bright's disease a retinitis or choroido-retinitis with more or less impairment of the vision, and in a small percentage of these cases detachment takes place The anatomic seat of the eye lesion in this disease is probably the blood vessels and as the supply vessels of the retina are end arteries any interference with their function is not compensated for as readily by collateral circulation as would be the case in other parts of the body So, almost always an extensive edema of the retina exists, which, owing to the loose attachment of that tissue, gives rise to the production of delicate folds in the membrane and later these may amount to a positive detachment, with its tendency to spread over the greater part of the fundus Occasionally, however, the detachment is brought about in a different way The vessel walls are sclerosed and weakened by the general disease, and any influence which tends to suddenly increase the blood pressure causes a rupture of the vessel wall with consequent hemorrhage, and the blood clot, if it be sub-retinal, produces a mechanical separation of the retina from its bed It would appear from the cases reported that detachment occurs most frequently in that class of kidney troubles in which we have to deal with what is known as the small granular kidney As very many of the reports, however, do not state the pathologic nature of the kidney lesion, it is difficult to arrive at any definite conclusions in this direction The above supposition, however, is what one would naturally be led to expect, as it is in association with the small atrophic kidney that retinitis albuminuria is most common Just as the retinal inflammation may occur in any form of nephritis, either acute or chronic, so may detachment be the ultimate result

The class of cases which probably offers us the most favorable prognosis is that occurring in the albuminuria of pregnancy, for here, if necessity arises the cause of the disturbance may be removed, and with that element withdrawn there is a remakable tendency to spontaneous recovery There seems to be no particular time in the course of pregnancy when we may anticipate retinal complications, as retinitis has been observed in every month, yet it is probably most liable to occur in the latter part of gestation, when the greatest tendency to general edema exists Schoeler reports cases of two sisters, both of whom suffered during pregnancy from detachment of the retina without any signs of albumin or retinitis

The following case of retinal detachment was related to me by Dr Randolph It is especially interesting as having occurred during labor The woman was the mother of eight children and always had easy labors Just before the birth of the ninth child her physician had made a thorough examination of her urine but had not discovered anything pathologic The labor was an exceedingly painful one and lasted for twenty-four hours At the height of one of her pains, and just after she had made a violent effort, she noticed that everything became blank before her right eye Since then she has been practically blind in that eye When seen by Dr Randolph there was nearly complete detachment of the retina in the right eye, the left eye being quite normal The case was seen a few days after the labor I think that the violent efforts and straining which she was constantly making led to a rupture of one or more of the retinal vessels which discharged their contents beneath the retina, thus forcing the latter away from the choroid, producing a detachment When we consider the frequency of subconjunctival ecchymoses following great efforts at stool or in children with the whooping cough, it is not strange that hemorrhage from the deeper vessels of the eye should have followed the violent efforts of a woman in labor

A few cases of detachment due to diabetic retinitis have been reported, but such cases are extremely rare, as diabetes is but seldom complicated by retinal disturbances

Galezowski found it, I think, in about 2 per cent of his cases, syphilis is given as the cause, and the same writer reports four cases the apparent result of sympathetic ophthalmia

Dr Mathew Owens of Brisbane, reported in 1884 two rather peculiar cases of double retinal detachment occurring in previously healthy eyes, as the result of sunstroke Both men were cattle rangers and the sunstroke was followed immediately by detachment The men were young and there was no history of any diseased condition that might have predisposed them to detachment In considering the cases Dr Owens offers the following as a possible explanation "It was shown by Boll that eyes which have been exposed to the influence of various colors are affected very differently as regards the pigment epithelium layer If eyes have been exposed to red or yellow, or kept in darkness, the pigment layer is quite easily separated from the retina, but not so if exposed to white, green or blue The retina and pigment are so closely united that they can not be separated The eyes of both patients had been exposed for some hours to the sun's glare, retinal hyperemia was present, sunstroke came on, the sinuses of the brain being engorged there was an impediment to the return of the blood to the brain from the congested fundus, effusion of serum took place, and the retina was quite ready to be detached because its pigment layer had been exposed to the yellow glare of the dried up ground" It is a rather unique explanation, and one which in my opinion is somewhat forced

Erysipelas of the face and neuralgia of the fifth nerve in a small number of cases, have appeared to be the cause of retinal detachment

Separation may be produced mechanically by hemorrhage or by sero-purulent exudates such as occur in purulent choroiditis or in phlegmon of the orbit Tumors in the choroid or retina, or a cysticercus developing beneath the retina may also be causative factors The tumors are usually glioma, or choroidal sarcoma

In every case of detachment the cause should be determined, if possible, because of its important bearing on the treatment Rydel has given statistics to show that 5 per cent of all our blind have become so from retinal detachment Despite the greatest care taken, however, in examining these cases, there still remain a large percentage in which no cause for the lesion can be ascertained In these cases the patient usually gives the history of having been perfectly healthy, with an eye that was either emmetropic or hypermetropic, and no exposure to injury of any kind The first symptom is a slight cloudiness of the vision, or a limitation of some portion of the visual field It is not attended by pain and it is only the loss of vision, more or less complete, that causes the patient to consult an oculist Some have thought that disturbances of the sexual nervous organization might be an explanation of a few cases, and in that connection quote Hutchinson as saying that "sexual abuse may produce degeneration of the vitreous," but I can find no case recorded where there is any conclusive evidence of this having been the cause Sudden suppression of the menses may result in hemorrhage, and that in detachment

The pathology of this affection has not been satisfactorily explained It was formerly held that the retina was pushed forward by a transudation from the choroid This hypothesis now has few adherents

A second theory, now generally known as the Leber-Nordenson, and which is the one most generally accepted, attributes the attachment to traction from the vitreous side The active cause here is held to be a shrinking of the vitreous, which ruptures the retina and permits the fluid from the vitreous cavity, pressed out by the contracting tissues, to pass through the rent into the subretinal space

This hypothesis assumes not only a shrinking of the vitreous, but an adhesion between the vitreous and retina and a rupture of the retina previous to its detachment

That rupture of this membrane necessarily precedes its detachment I do not believe I can not see the need of this supposition in regard to a tissue so loosely attached to its bed as is the retina, and, furthermore, if it does always occur we should be able to see it in a greater number of cases In a very large percentage seen, even in early stages, it is impossible to find a rupture and even Leber, who considers it so important to his theory, found it positively, in relatively fresh cases, in only about 50 per cent

It may be that in some cases, at least, the change in the vitreous humor is a chemic one, which leads to an interchange of fluids between that body and the blood vessels of the choroid, and that detachment is produced in accordance with the diffusion theory This theory, so ably advanced by Raehlmann, has not received the consideration it would seem to merit

Though the immediate cause of displacement is so obscure it is probably safe to say that the vitreous is always the seat of pathologic alteration, though such changes may not be, and often are not, apparent by ophthalmoscopic examination One can hardly conceive, except in case of intra-ocular growth, or of sub retinal hemorrhage, of detachment occurring when the vitreous is of normal consistency and exerting its usual pressure on the surrounding parts

---

TREATMENT OF DETACHMENT OF THE RETINA

Read in the Section on Ophthalmology, at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Ga , May 5 8 1896

BY CASEY A WOOD, M D

CHICAGO ILL

Without taking your time with a historical sketch of the various remedies employed in the treatment of detachment of the retina I may say that the earliest efforts of the ophthalmic surgeon were directed to puncturing the subretinal sac as it was found that this usually brought the displaced membrane into its normal position As, however, the detachment was found to occur a second or a third time or, indeed in many cases, as often as it was replaced, various expedients were resorted to with the hope of rendering the cure permanent

Before speaking of these matters in detail let me remind you that replacement of the membrane does not necessarily mean a restoration of the lost visual function, although it is a *sine qua non* of that restoration Nor do the visual acuity and the extent of the visual field form a proper measure of the success of a remedy for detached retina *as such* A badly damaged retina (as in the long standing cases) perfectly replaced may give results much less satisfactory to the patient than an imperfect replacement of an other wise healthy membrane—such as we commonly find in recent examples of this disease

I pass over the treatment by rest in bed, with or without such adjuncts as bandages, the local use of eserin and atropin, the internal administration of salicylates, purgatives, diaphoretics, potassic iodid, pilocarpin injections, starvation, iridectomy, sclerotomy and puncture of the sclera, to take up certain other surgical proceedings that are now claiming attention as being more or less novel

I had been attached for nearly a year to Professor Schöler's Klinic in Berlin when he first began to experiment with intra-vitreous injections of iodin in this disease Consequently, I have had excellent opportunities of observing its effects Although much was hoped and expected from the procedure and a number of cures have certainly resulted from its use, the evidence is on the whole against it as a dangerous and by no means certain remedy That numerous eyes have been entirely lost from the employment of Schöler's method, I am obliged to confess, and I do not think that, even in its modified form, one would be justified in employing it Most of you will also recollect Gelpke's experience The patient, a healthy man, 66 years of age, with detached retina, received under strict precautions a vitreous injection of three drops of iodin mixture *In two days he had a purulent choroiditis* and in six days he died of acute meningitis

Other less active and more certain expedients may be employed to produce all the effects which Scholer claims for the iodin injections We may dismiss, also, as needless and dangerous, the injection of irritating fluids—such as potassic permanganate, suggested, I think, by Darier—through a puncture in the sclera To this category, too, belong De Wecker's device of a gold suture and Galezowski's catgut suture, all three intended to produce local inflammatory areas and so bind choroid and retina together

Wolfe of Glasgow, made a long incision (6–10 mm) through the sclera, the underlying conjunctiva being pulled away by hooks, and so obtained free and con tinued drainage of the subretinal fluid In fifteen eyes he had improved vision (lasting five months to a year) from ½ to 1-50, in five cases the results were *nil*, and in two instances the eyes were lost Even when performed under strict aseptic precautions the danger of infection through these large wounds must be considerable

Gillet de Grandmont first advised electrolysis of the subretinal fluid Simi of Florence, among others has successfully tried this method in a case of recent detachment, using a 5 milliampère current for sixty seconds, and two weeks subsequently the same current for seventy seconds There were signs of reaction in both iris and vitreous and the exudation disappeared, but the detached portion remained opaque and was clearly outlined from the healthy retina by a pigmented line

Terson of Toulouse, from a study of twelve cases in which he employed electrolysis of the post-retinal fluid, believes that the method of Gillet de Grandmont with a single needle attached to the positive pole is superior to those of Abadie and Scholer, the latter of whom employed the bipolar plan—making two punctures in the globe

Posterior Ophthalmotomy—Galezowski[1] formerly relied on iodin injected into the post retinal pocket (1886) with aspiration of the contained fluid If necessary he followed this with a catgut suture, passed like De Wecker's earlier gold stitch, through all the eye coats This latter procedure usually succeeded in binding the retina to the choroid but as it was followed in two instances by severe intraocular inflammation he abandoned it in favor of the operation which he now recommends as free from danger and quite as successful He calls it posterior ophthalmotomy The instrument used is in the form of an arc of a circle, like a curved needle, so that a sufficiently large puncture and counterpuncture can be made and a sufficient number of retino choroidal cicatricial points produced to keep the detached membrane in place when it has once returned He has already followed this plan some seven times—in five cases with partial, in two with great success In one instance of a man aged 50, with a double detachment, of long standing on the left side, but recent on the right, he obtained a complete cure in six weeks The linear cicatrices could be made out with the mirror, the visual field and central acuity were very greatly increased

Probably the most recent, original and important contribution to the rational treatment of retinal detachment has been made by Deutschmann of Hamburg, which first appeared in his *Beitrage zur Augenheilkunde*, although he has since (in May, 1895) given an abstract of the brochure in the *Deutsche med Wochenschrift* He prefixes the account of his methods by a reference to Erik Nordenson's work with Leber

Apart from certain rare forms of the disease, detachment is due not so much to a primary deposit of water from the choroid behind the retina as to the dragging upon this coat by a diseased and shrinking vitreous The detachment is merely one of the signs of the vitreous disease Nordenson shows that without losing its transparency the vitreous develops a fibrillar quality, decreases in volume and in shrinking allows the vacant space to be filled with serous liquid This change in the consistence of the vitreous body is not unfrequently accompanied by proliferation of the vitreous elements as well as by a chronic inflammation of the choroid Portions of the thickened vitreous remaining firmly attached to the retina are, with it, liable to be dragged toward the center of the posterior chamber Deutschmann's first proceeding, which he names *Netzhautglaskorperdurchschneidung*, is intended to sever all connections between the shrinking vitreous and the retina, to allow of a free communication between the posterior chamber and the serous collection behind the retina, to empty the latter space so that the freed retina may return to its normal position, and lastly, to produce adhesion between choroid and retina at certain points, these indications are met by the following operation The previously atropinized eye is cocainized and a double edged knife, of the Graefe pattern, is introduced at the chosen spot, the conjunctiva being pushed to one side It pierces all the ocular coats, sclera, choroid, and the detached retina Thence the knife is passed obliquely through the vitreous mass until it touches the opposite wall of the bulb It is now carefully moved to and fro toward either side making a vitreous discission and is finally removed, and a light occlusive and antiseptic bandage applied Slight hemorrhage occurs at the point of entrance of the knife and inflammatory action is set up about the incision points in both choroid and retina This latter process is relied upon to permanently fix the retina to the choroid and so resist any subsequent pulling of the vitreous

The patient is now kept in bed for eight to fourteen days, until the ophthalmoscope shows that the case is cured The atropia is continued for several weeks longer When the retina does not lie perfectly flat on the day after the operation, a delay of a few days may be made in the hope of its complete return to the normal position If this fails the same procedure is to be resorted to, as often as is required, until the desired effect is obtained Deutschmann has operated ten times upon the same patient with good results at last He thinks that repeated thrusts of the knife are safer than, and as effective in inducing a sufficient degree of adhesive inflammation between the retina and choroid as the application of the Paquelin or electro-cautery point to the sclera, or, piercing that also, to the choroid and displaced retina beneath

He refers in his short article in the *Deutsch med Woch*, to eleven patients treated by him, to date Upon four the Paquelin cautery was employed and the sclera pierced Of these four, two were partially relieved and two not benefited Of the remaining seven, where the cautery was omitted, total replacement of the retina was obtained in six instances, with decided improvement in vision This satisfactory condition has persisted in one case for four years, three cases two years, one case one year and one five months In the case, where least benefit accrued, only one operation was made, the patient declining further interference

The author advises this operation in those more favorable cases, where the displacement is recent and not too widespread and where disease of the coats is not advanced

In another class—in their nature more hopeless—he has employed quite a different and novel remedial process, which he styles "*Kaninchenglaskörpertransplantation*" This was first tried on a patient 28 years of age, with bilateral detachment of the retina The left eye had suffered a sudden and total separation of the retina from the choroid The eye was soft and vision was reduced to perception of light in the upper part of the field Both anterior and posterior retinal spaces were filled with a sero-sanguineous fluid Deutschmann removed this bloody serum and with an ordinary hypodermic syringe injected into the empty vitreous cavity the freshly prepared, aseptic vitreous of a young rabbit, diluted with a $\frac{3}{4}$ per cent solution of common salt The addition of the sterilized salt solution was intended to allow of easy flow of the vitreous as well as to act as an irritant and bind the choroid to the retina The result was marvelous The operation was performed Feb 4, 1894 On April 28, V = $\frac{15}{200}$, on July it was $\frac{15}{70}$ and Jäger No 3 F of V for white was uncontracted and has so continued

Deutschmann has, to May, 1895, performed this operation on six patients and seven eyes, and in four obtained results that hitherto would have been regarded as impossible In all, central vision before the operation was reduced to perception of light or shadows and most of them were cases of total detachment

---

[1] Galezowski Mem et Bull de la Soc frs 1895 p 170

In case 2, which was of many years standing, there was beginning secondary cataract, V= eccentric finger-counting at four feet Result Useful central vision, replacement of the detached retina and enlargement of the eccentric field to twice its previous size Case 3, total detachment from injury V= hand movements Visual result not very encouraging V=finger counting at 2 and 3 feet eccentrically

In the other cases the result was uniformly favorable The patients have been under observation for from a year in Case 1 to five months in Case 6 after the replacement of the retina This operation may have to be repeated two or even three times and it must be remembered that an inflammatory reaction follows each injection

Detachment of the retina does not occur often in this country, but I have on my records six cases that consented to be treated for a sufficient length of time to make my experience with them worth mentioning The treatment for two scleral punctures, one iridectomy and the other three had prescribed for them continued rest in bed with pilocarpin injection Only in one case, treated by puncture and pilocarpin, was there a permanent cure, the retina being replaced, the visual field expanded, and the central vision now equals finger counting at seven feet, although at one time it was reduced to perception of light This continued for nearly a year, when I lost sight of the patient My experience of this disease in my own practice, public and private, and in that of others lead me to think, with Bull of New York, that we have as yet discovered no better device than that resorted to with occasional success by the older ophthalmologists, viz rest in bed, bandages, atropin and the internal use of some absorbent Instead of the long continued use of pilocarpin, especially when that drug is ill borne by the patient, we may substitute soda bicarbonate and potassic iodid, well diluted with water In all recent cases where the eye is quiet and there is no vitreous strand to sever, conjunctival puncture of the sclera may do temporary good and vision may be improved Division of fixed membranous bands in the vitreous may be done without causing much reaction and may prevent extension of the disease He does not approve of Schöler's method

In conclusion, this review of the treatment of detached retina would be incomplete without a reference to spontaneous cures Many such cases are recorded, indeed one may safely say that of all the histories of cures, temporary and permanent, at least 10 per cent were accomplished without treatment So numerous and well authenticated are they that I think that a large percentage of the results obtained after iridectomy, after removal of the lens, from the use of atropin, bandaging, pilocarpin, etc , even some cases of cure following posterior operation, are really brought about by local and general rest—by putting patients in such a position that they can not by over exertion of any kind make a bad matter worse The retina, having meantime broken loose from its connections with the shrinking vitreous, returns to its natural position—and the treatment, medical or surgical, receives the credit

This is the *proper season* to increase the membership in the Association Let everyone secure *one!*

REPORT OF A CASE OF RETINAL DETACHMENT AND EDEMA OCCURRING IN CHRONIC BRIGHT'S DISEASE

Read in the Section on Ophthalmology at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga May 5-8 1896

BY LOUIS F LOVE, M D
OPHTHALMIC SURGEON TO ST MARY'S HOSPITAL, HOUSE OF GOOD SHEPHERD ETC
PHILADELPHIA, PA

When we take into consideration the blood conditions existing in albuminuria, it seems strange that the occurrence of retinal edemas and detachments are not more frequently found The vitreous body is undoubtedly nourished from its surroundings, and Raehlman long ago demonstrated that by injecting strong salin solutions into the vitreous he was able to produce retinal detachment and that the fluid secreted was densely albuminous, so that it seems rational to say that any cause which produces profound changes in the circulation would interfere with the balance of osmosis between the vitreous body and the choroidal vessels I believe that by a careful chemic and microscopic examination of the general blood conditions, especially the liquor sanguinis, we might be able to benefit, at least, some of our patients to whom we are at present useless In detachments taking place in high myopias or resulting from inflammatory conditions, this line of investigation would be of no avail, but in those cases arising without apparent cause, such as we occasionally see in emmetropic eyes, that such a research might be of use This case is reported for the reason that it is not only rare, but because of the unusual prolongation of life

C D, a short, stout woman, aged 54 years, applied for treatment Oct 26, 1892, giving the following history Had always enjoyed good health Lately slight headaches and dyspnea upon exertion She is the mother of five children three living, no miscarriages, menopause at 46 Four years ago her vision in her right eye failed suddenly About two weeks ago she noticed a dimness in the left eye The present eye conditions were as follows O D V = counting the fingers at ten inches O S V = $\frac{20}{70}$ + S 2D = $\frac{20}{30}$ + S 4D type 1D 12c to 25c The eyes are rather deeply set, ocular and tarsal conjunctiva pale, the arcus senilis well marked above, the color of the irides brown, right pupil 3 mm and very sluggish to light, left pupil about $2\frac{1}{2}$ mm , active to light Anterior chambers shallow, strong reflexes from both lenses Right eye Tn — left Tn

Ophthalmoscopic examination O D A few very fine floating vitreous opacities, the nerve decidedly atrophic, the vessels diminished in size and a retinal edema extending well out when an extensive retinal detachment was plainly seen superiorly and inferiorly, giving the characteristic delicate gray undulating tremulous protruding membrane The vessels could be traced from the papilla out into the detachment, and in places showing sharp bends and partially hidden from view by the folds of the separate surface The disc is seen best with + 3D , the detachment with about + 7D Left eye lens seemingly hazy, disc very red gray, veins slightly enlarged, arteries normal in caliber, carrying poor blood, a large area of hemorrhagic extravasation in the macula region and a few white plaques found just above the disc H = 4d

Examination of the urine was as follows Straw color, acid, specific gravity 1018, albumin in moderate amount, no sugar, microscopic examination hyalin casts, pus cells and few blood corpuscles

The patient was under the care of Dr J C Wilson, who saw her on four or five occasions, between Nov 1, 1892, and March of the following year His *report to me was as follows* There was cardiac hypertrophy, accentuation of the aortic second sound and slight pre-tibial edema She *improved in* respect to the headaches and restlessness while under treatment by strychnin and nitroglycerin, together with a carefully regulated dietary

The woman was not seen again until Nov 6, 1895, three years after the first examination O D V = light perception only O S V $= \frac{20}{70}$ + S 2D V $= \frac{20}{30}$ Ophthalmoscopic examination shows vessels thread-like in the right eye, apparently similar conditions of retina as existed when first seen The left eye, the nerve quite gray, vessels about normal in size, in the macula region a brownish black area, and above the disc there are characteristic changes of an old retinitis Brightii The patient states that her general condition is about the same, enjoying fairly good health, she has taken no treatment since March, 1893, but adheres somewhat to the regulated dietary as ordered by Dr Wilson

1762 Frankford Avenue

DISCUSSION ON PAPERS OF DRS RANDOLPH, REIK, WOOD, AND LOVE.

Dr J A White, Richmond—In considering the etiologic *factors of detachment we are to some extent groping in the* dark Apart from myopia, tumors, subretinal hemorrhages and effusions, I do not think we have any very sure foundations for explaining the many cases we meet with where there is no apparent cause whatever It is important to know the cause in order to decide upon the method of treatment, but in many cases this can not be established When we come to consider the treatment we are still as badly off as we were many years ago The old treatment of rest, diaphoretics, pilocarpin, etc , give us as good results to day as any of the operative procedures It is only in the recent cases of detachment *that we have had any satisfactory results from any of the* methods I have tried rest, iridectomy, sclerotomy, paracentesis and sclero puncture I do not advise operative measures except in recent cases where the macula is involved, and even then I do not if there exists a condition *likely to lead to* hemorrhage Electrolysis may be a good thing, certainly much has been claimed for it The galvano cautery is too dangerous, and should be placed in the same category as the injections of iodin Deutschmann's method has been mentioned, but neither he nor anyone else has had sufficient experience with it to warrant very favorable reports One method that has *not* been mentioned here is that of Strau He frees the conjunctiva from the sclera over the site of the detachment, makes three little slits in the sclera, and then unites the conjunctiva over this with sutures and allows it to heal He then makes *injections in this* region of a 1 5000 bichlorid solution, and has claimed very good results It is simply an experiment, like all the others, and may be discarded I have not tried the injections of rabbit's vitreous according to Deutschman I have watched a few cases in private practice *from their start* One was in a physician and associated with myopia He has a low grade of *myopia* and wears a —2 50 D for distance, and with it has had for fifteen years almost perfect vision Recently he said that he had a little spot in his eye, I paid no attention to it, thinking it simply a musca volitans Some time later he complained of an increase of this spot, but I could not find any opacity with the ophthalmoscope Later a slight spot became visible, looking like a floating string, and I then told him that his vitreous was undergoing liquefaction, though he never had any alteration of the refraction or any changes in the choroid that I could determine Soon I noticed a secondary detachment, and although we gave treatment by rest, pilocarpin, etc , at once, in sixty days the detachment was absolutely total He from the first refused an operation, because he was well acquainted with the subject, and knew the slight chances of success

Dr Lyman Ware, Chicago—I did not for a moment question the correctness of the report of Dr Terson's cases, but I was not convinced that electrolysis was the cause of the result Is the using of a positive pole a rational treatment? One of the first things settled in regard to the use of electricity was that the *positive pole produced coagulation* and the negative pole diffusion *Would not absorption be best brought about* by the use of the negative pole? The fact that we have such a variety of treatments offered shows that none are very satisfactory

Dr A R Baker, Cleveland—I wish it were possible to make a more scientific classification of these cases In the case of hemorrhage, tumor or trauma the detachment is simply an incident, and in those cases produced by Bright's disease, if the cause could be removed the case would recover Formerly *I made a sclero puncture, but lately I have omitted that* Besides rest I give them diaphoretics, and in some cases we have found considerable benefit One case where there was almost complete detachment in one eye existing for a number of years was followed by detachment in the other eye I kept him under treatment for six months, and discharged him with fairly good vision About three years later I found him back in the hospital, *blind* and without *any prospects of recovery* Treatment is very unsatisfactory

Dr G E De Schweinitz, Philadelphia—I would deprecate the report of cases of retinal detachment submitted to operative interference, before sufficient time has elapsed to test the *sufficiency of their cure* I would suggest that Deutschmann's result in human beings with injections of sterilized vitreous be repeated in animals

Dr D S Reynolds, Louisville—I am unprepared to accept the details of the pathologic changes described by Dr Randolph *It is by* no means clear that the drawings furnished are sufficiently accurate to support the accompanying descriptive language The normal retina can not be shown to contain pigmented layers, yet Dr Randolph's report contains a reference to that impossible condition In my own experience *results have been in some cases very encouraging at first*, but in a few months fatal relapses have occurred In persons under fifty years of age, in good robust general health, medicinal treatment often yields brilliant results, but in nearly all cases subsequent return of the detachment of wider areas surely comes on in due course of time I have seen it most always in myopes, but never in any but progressive cases My attempts at operative treatment have yielded results in no wise more encouraging than that by the salicylates, pilocarpin and the iodids, *with rest in bed* Much *remains yet to be done* before we may claim any permanent recoveries from any treatment

Dr R L Randolph—While nothing positive has been added to the therapeutics of this subject, I think we have gone over the whole field thoroughly, and it is always a help to know the present status of any subject

Dr A R Baker, Cleveland—The question has often been suggested to my mind whether we have detachment in this class of cases I have seen but few *except* in high degrees of myopia, and become so accustomed to think of it in this way that I have almost quit looking for any other cause

Dr F W Higgins, Cortland, N Y —In looking up the subject of edema of the retina in Bright's disease, I noticed one cure reported by Brecht (*Archives f Oph* , Vol xviii, 2 p 102) of marked detachment of the retina *in nephritis* He considers it very rare and due to some p [illegible] tion

THE USE OF CAUSTICS FOR EPITHELIOMA OF THE LIDS

Read in the Section on Ophthalmology at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY FRANK TRESTER SMITH, A. M., M. D.
PROFESSOR OF DISEASES OF THE EYE CHATTANOOGA MEDICAL COLLEGE FORMERLY ASSISTANT SURGEON NEW YORK OPHTHALMIC AND AURAL INSTITUTE
CHATTANOOGA, TENN.

This subject was suggested by the following case which came under my observation.

Frank S., age 64, of Chattanooga, at the age of 43 had had the right eye destroyed by an explosion. The ball was shrunken and the lids adherent, so that this eye was entirely useless.

The left upper lid presented an ulcer about one-third inch in diameter covered with a dry scab, on the inner and outer sides there appeared to be a blister. The trouble began twelve years ago from a small scab which was picked off from time to time and the ulcerated surface had gradually grown larger. A few days before, some empiric had made an application which had caused the ulcer to double in size, after which the borders had become blistered. A soothing application was prescribed with the idea that the blisters would disappear, but the bases became hard and the contents gelatinous. The case did not improve after several weeks' treatment. The diagnosis of epithelioma was made, and an operation, consisting of the total removal of the inner half of the lid and supplying its place by a plastic operation, advised. The patient was myopic and presbyopic. Left vision 20-200 with 2 dioptry concave lens 20-70. While preparing for the operation the patient came under the care of an empiric who by means of some caustic, apparently destroyed the pathologic growth, and it was replaced with a smooth cicatricial tissue, leaving the lid intact and much more useful and ornamental than any plastic surgery could have devised.

The case suggests that in some cases of epithelioma of the lids, especially where we can not operate, that caustics should be used. In this case the pathologic tissue extended so as to require the removal of the entire thickness of the lid by any cutting operation, and any surgeon would certainly have removed at least half the lid and even then there would probably have been a reappearance of the tumor. Nearly all this was removed and the lid left in good shape, with the loss of a small amount of tissue, by the use of caustic in unskilled hands. It can but suggest that if the caustic had been carefully and thoroughly applied the cancer cells would have been thoroughly destroyed.

Dr. A. R. Robinson, of New York, called attention to the advantages of the use of caustics in the treatment of cutaneous epitheliomata in an instructive paper read before the Tri-State Medical Society of Alabama, Georgia and Tennessee in 1895. For use about the eye he recommended a solution of chlorid of zinc in a 20 per cent. solution of cocain.

The objection to the use of caustics, in this location, is that some of it may come in contact with the eyeball and cause ulceration. For this reason these growths are removed by cutting.

The advantages of the caustic over the knife are that there is usually less destruction of tissue, and with the destruction of the same amount, the result is surer, because the necrosed tissue is surrounded with an inflammatory zone and the products of the inflammation tend to destroy the pathologic cells for a distance beyond the part extirpated. This is more likely to be the case if the wound is allowed to suppurate, as it is generally conceded that the toxin of germs which produce suppuration are destructive to the cells of epitheliomata.

Some of the caustics have an elective action on the cancer cells. This is notably the case with arsenious acid, which should be used weaker than in Marsden's paste, three parts of acid to two of gum acacia. It is said this will not attack normal tissue for twenty hours. It is believed that by having the case under constant observation during the application, that caustics can be used safely on the lids, in many cases, to the advantage of the patient. I am aware that this position is opposed to that of most oculists but I have been told that some of the members of this Section have used caustics instead of the knife. However, I have been unable to find any literature on the subject.

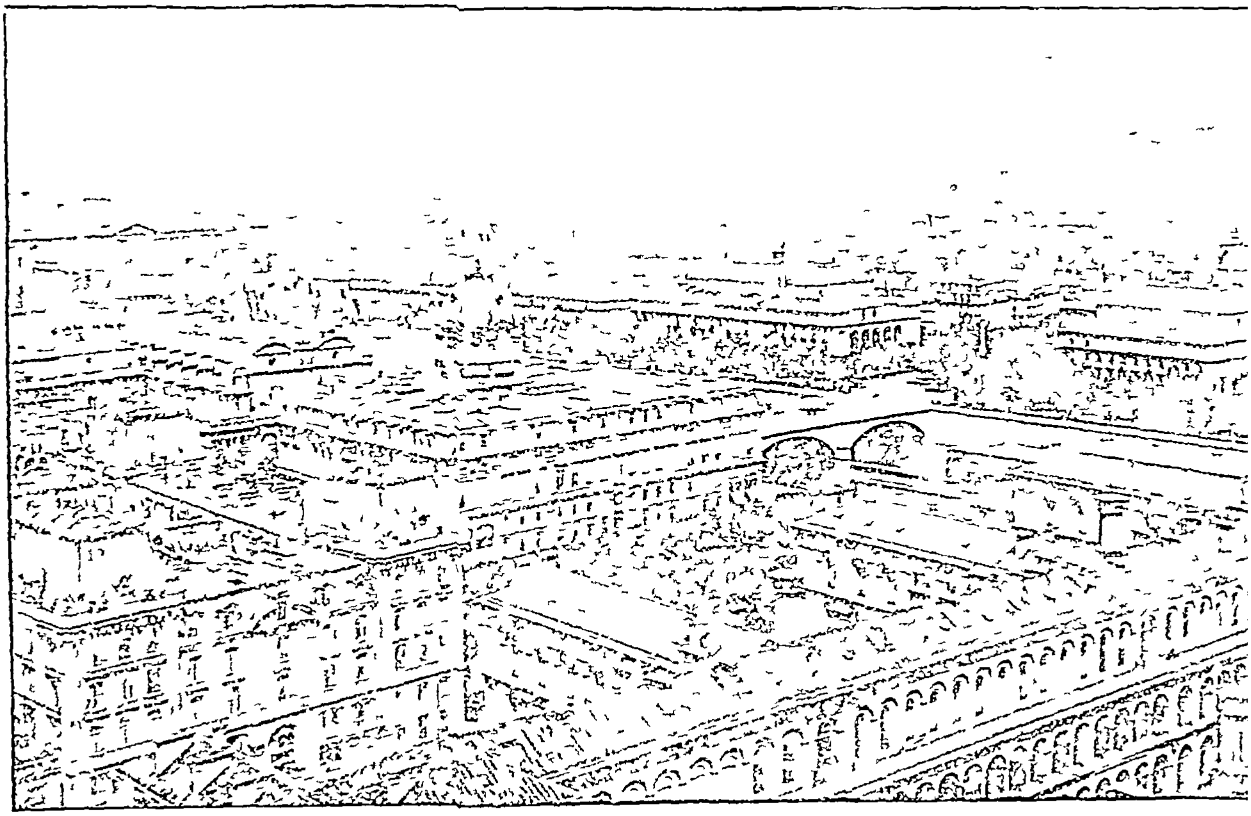
MEDICAL PARIS

NOTES FROM MY SKETCH-BOOK

BY L. HARRISON METTLER, A. M., M. D.
CHICAGO, ILL.

In his powerful romance, "Les Mystères de Paris," Eugene Sue, who, by the way, was a physician and the son of a physician, paints a vivid picture of Parisian low life, locating most of his scenes in the crowded tenements and narrow alleys which once occupied the ground now covered by the immense buildings of the Hotel Dieu. When these buildings were constructed, only a few years ago, the remains of the historic Hotel Dieu, as well as many another ancient landmark, were swept out of existence. The Ile de la Cité, with the noble old cathedral of Notre Dame, the gruesome Morgue, so strangely fascinating to Dickens, the Hotel Dieu, so often pictured in history, poetry and romance, the Palais de Justice, the oldest monument in the city, and the matchless Sainte Chapelle, the gem of medieval architecture, constitutes only a small section of modern Paris, but it is the richest in historic lore and romantic anecdote. In one of the ancient streets, now vanished on account of the encroachments of the Hotel Dieu, dwelt the shrewd physician, Theophraste Renaudot, who, in 1630, printed the first Parisian newspaper, *La Gazette de France*. The wily Theophraste had observed something of the power of human curiosity and had cunningly undertaken to gather news from all quarters for the amusement of his patients. Of course his clientage rapidly increased and in a short time he was more in fashion than any of his practicing brethren. But all Paris could not be expected to be on the doctor's sick list at the same time, and were even such a pleasant thing possible his suite of apartments would not be able to accommodate such a glorious rush of practice. Accordingly the doctor decided to publish weekly some fly sheets, containing the latest news from other countries. For this he needed a license and obtained it *cum privilegio* in 1632. The success of the venture surpassed the most golden dreams of even the medical imagination. Similar fly sheets had already been issued in Venice, for which a small coin, *una gazzetta*, was asked, whence comes the name of our modern gazettes.

One day as I was coming out of the Hotel Dieu, a student, with whom I happened to get into conversa-



PARIS, LOOKING NORTHWEST FROM THE TOWERS OF NOTRE DAME CATHEDRAL HOTEL DIEU IN THE FOREGROUND

tion and to whom I had just mentioned several special clinics which I had learned were to be given, asked me where I obtained my information in regard to all these things Of course I told him and then wondered if old King Clovis did not turn over in his grave to think that a Chicagoan must needs inform a descendant of the proud Franks in regard to his cherished Maison Dieu The Hotel Dieu Hospital, or God's Hostelry, known in early history as the Maison Dieu, is said to be the most ancient hospital in Europe The actual date of its foundation appears to be in doubt though there are reasons for thinking that it had its origin under Clovis, King of the Franks, who flourished during the latter half of the fifth century Saint Landry, who was Bishop of Paris about the middle of the seventh century, is the reputed founder It is probably this hospital that is men*tioned under the name of St Christophe in a charter* of 829 The Maison Dieu was not the direct offshoot of a monastery, as many other hospitals were In accordance with the decree of Charlemagne, promulgated in 816, that at each See one of the canons should govern the hospital, and that the latter should always be near the cathedral, the Maison Dieu was erected within the shadow of the Notre Dame cathedral and was, until quite recent times, under the control of its chapter At first it was more than a mere harborage for the sick It was a charitable organization, embracing every form of aid to the poor and outcast The first building to bear the name of Hotel Dieu, on the south side of the Place du Parvis Notre Dame was commenced by Philippe Auguste who named its first ward the Salle St Denis Queen Blanche of Castille added the Salle St Thomas It was then almost entirely rebuilt by St Louis who added especially the Salle Jaune and two associated chapels on the river bank For nearly a hu years after this it was wofully neglected, but Louis XI ascended the throne its prosperity re This king did much to favor it, and built the e itely beautiful gothic portals of the two chapel the Petit Pont, which, together with the el renaissance gable belonging to the Salle du were the particular artistic features of the bu until its destruction by fire in December 1772, many of the sick inmates perished and the rest hastily received by the archbishop in Notre Henry IV added two wings and greatly increase revenue of the hospital Were it not for the fri loss of life and the burning of the charming ch the destruction of the old hospital was a blessing than otherwise It was small, badly arranged anything but architecturally beautiful Victor *describes its front as "furrowed and rugged"* says its roof from the tower of the cathedral lo as though it were "covered with pimples and wart

The next building that was erected to take place of the old Hotel Dieu was devoid of all sp *features in the way of art and architecture* little effect it did produce upon the artistic eye completely lost by its juxtaposition to the cathedral It consisted of several irregular mas buildings and its portal, erected in 1801 after des made by Clavereau, was severely plain and Dor style Beneath its peristyle stood the statue of philanthropist Montyon, who was buried (1838) according to his desire in the midst of the poor sick *It was in this building also that the fin* poet Gilbert died in 1780 In the reign of Louis the over-crowded condition of the hospital was a grace to the city of Paris and to the science of m cine The monarch attempted some relief by erec four auxiliary establishments in the suburbs, namely, the St Louis Hospital, the St Anne Hospital, the Hospital for Incurables and the Hospital for Convalescents. A horrible picture of the wards at this time was given by Tenon, the president of a committee of investigation appointed by the Academy of Sciences. Convalescents were seen by the local commissioners in the same room with the sick, the dying and the dead. The insane were confined in neighboring rooms and apartments and kept the other wards in a continual state of excitement with their ravings. Operations were performed in the same room or ward in which there were beds containing other patients. In the days before the use of anesthetics we can well imagine that the cries and contortions of those undergoing operations would have anything but a favorable effect upon the other patients. During the French Revolution the name of the hospital was changed to L'Humanité. Finally the whole conglomeration of inadequate and unsightly buildings was demolished, an increased area was secured and the present vast, homogeneous and elegant edifice was inaugurated in August, 1877, under the direction of the architect Diet. It is an immense oblong stone building surrounding a courtyard of ample dimensions. The arrangement of the wings, gridiron-like, is the happiest imaginable for the introduction of air and sunlight into the interiors. Overlooking the courtyard is a peristyle or open porch all round the building where convalescents may sit in the open air. The work of the hospital comprises a service of about 810 beds. Of these 430 are for men and 380 for women. Medical cases take up 555 beds while 255 are given over to surgical cases. The history of the government of the hospital is interesting. Until 1505 it was under the management of the chapter of Notre Dame. After that year it was looked after by a committee of lay governors, eight in number, selected from the citizens of Paris. The selection was made by the mayor and aldermen and the appointments confirmed by the parliament. In 1654 the number of directors was raised to twelve. In 1690 Louis XIV made some alterations in the government and formed the Grand Committee, including in that committee the archbishop of Paris, the former presidents of parliament, of the taxation court, of the court of alms, the commissioner of police and the mayor. To-day it is under the control of the Assistance Publique, one of the departments of the Prefecture of the Seine, as I explained in my last sketch. The oldest paper in its rich collection of archives is dated 1157, and from 1531 to the present there is a complete unbroken history of its work. Such is the story in brief of God's Hostelry, Paris, the oldest hospital in Europe, and one of the greatest in the world. Within its walls medicine has had one of its firmest strongholds and from its wards have issued many discoveries in science. Did I say the poet Gilbert died here? Many another poet has died here too, yea, and statesman and artist and soldier and king, whose names have never been emblazoned on the escutcheon of fame. Sickness is a great leveler of the human race, births and deaths emphasize the equality of man. A hospital is a place for thought, a great hospital awakens reflections that only eternity can answer.

As a frequent visitor to the Hotel Dieu I was intensely interested in some of the differences between French and American hospital methods. One day I accompanied a group of students, who were being instructed by the surgeon Kermisson, a spare, active, wiry sort of a man, who always wore a skull cap, through the wards. The operator hastened from one bed to another, examining this patient, performing a slight operation upon that one, prescribing for another, while the class arranged themselves as best they could about the foot of the bed, to see and hear what was being done. This walking through the wards has clearly its advantages for the student but disadvantages for the patient. The latter is excited and made nervous and it seemed to me was unnecessarily exposed to the contamination and germs of disease brought in by the students from the street. When an operation was to be performed a screen was placed by the attendants around a table at one end of the ward and the patient carried from the bed to the table. The patient, especially if it were a child, would scream and kick and thus disturb the entire ward. The morning visits of the staff were therefore always a time of excitement and turmoil, and in many respects the manner of them seemed to me to be unfortunate and primitive in the light of the scientific knowledge of the present day. Among the group of students, men and women, about twelve or fifteen in all, elbowed one another for a closer view or rattled their tongues in chatter like flying shuttlecocks. Modesty appeared to be an unknown quantity in such a group, science and knowledge alone were the guiding spirits. The exposure of the patients was at first something quite shocking to an American's sense of delicacy.

Upon another occasion at the end of a long ward I found a tall Japanese screen, behind which stood an operating table with a woman on it undergoing electric treatment for a fibroid tumor. Apostoli, to whom I had just been presented, was managing the operation himself, while the students pushed and crowded against each other, jammed their way in and out or stood tip-toe, craning their necks unmercifully to get a glimpse of what was in progress. My sympathy went out for the poor woman, for she was of enormous dimensions, and that with a goodly sized tumor thrown into the bargain must have made the journey of life for her a matter of no mean affair. And then to think after carrying all that flesh and blood along the rugged *via vitæ*, to fetch up at last upon an operating table at the end of a long and crowded hospital ward, with half a dozen men performing a private examination upon her and a dozen or more idle, curious French students (plus one American) looking on! Strange, indeed, are the destinies of some folks! For the happiness of her fleshly mortality I hope the tumor was reduced, but I have my doubts about it, never having yet seen so fortunate a termination in the electric treatment of fibromata. Apostoli, whom I afterward had the pleasure of meeting at a banquet and reunion of *Des Trente*, a non-professional society of congenial ladies and gentlemen, given by way of novelty upon the first stage of the Eiffel Tower, I found to be most enthusiastic, yet sufficiently conservative in regard to the possibilities of electricity. His ideas have been so extensively published that it is unnecessary for me to dwell upon them here.

Of the staff of the Hotel Dieu, the acquaintance of none afforded me more pleasure than that of the late Professor Germain-Sée and of the distinguished surgeon Tillaux. The first time I met the former, he was seated at a small table surrounded by several students in one of the medical wards He bore his years remarkably well and his kindly old face lighted up with a pleasant smile as he chatted about America and some of the good that was being accomplished by us He was not a large man nor imposing in manner His countenance was round and friendly, his head was bald and he wore close cut side whiskers, leaving only the front and under part of the chin clean shaven In accordance with the law of the hospital, Germain-Sée should have been retired many years, as he was past the age at which the government allows a man to hold a hospital position So great, however, had been his services to medicine and so distinguished was his name, that an exception was made in his case and an extension of his time gladly granted His didactic lectures were always well attended In a small and poorly lighted room his class usually assembled, while he himself with one or two assistants would be seated behind a long, green baize covered table He always remained seated while lecturing, making use occasionally of brief notes His style was ideal for a scientific discourse It was decisive and clear-cut, and as the speaker leaned over the table toward his hearers and emphatically voiced his dogmatic opinions one could not help admiring the preciseness, the optimism and the fertility of resources evidently acquired by long years of valuable experience in contest with disease At times sparks of gentle humor would flash out of the discourse It was always a quiet, incisive sort of wit, rather than a broad rollicking humor Instead of a peal of laughter, it would merely produce a lively titter among the students, which would subside as quickly as it had arisen

In physique, disposition and manner, Tillaux is the very type of the old time surgeon, large, portly, full of inspiring confidence, moving about with a heavy tread and always speaking in an assertive, commanding tone of voice To "assist" (a word used by the ever-polite Frenchman for one who is merely a visitor) him in one of his morning visits to the wards of the hospital is good surgically and psychologically I was more than once inclined to wish that some of our younger surgeons had somewhat of the old-time dignity and courtliness about them It would not add one whit, of course, to their skill, but it certainly would lend a grace and pleasing manner to their noble art, and it would have somewhat of a beneficial effect upon the unstable, nervous condition of many of their patients Appearances count for something sometimes I would that I had space to relate more of what I saw at the famous Hotel Dieu, but I would then have to omit another great hospital, probably better known than the Hotel Dieu and that without doubt through the association of the world-renowned Charcot

From his residence, a typical elegant French apartment on the Boulevard St Germain, not far from the artistic Pont de Solferino the late Professor Charcot was wont to drive in his handsome brougham and pair every morning between 9 and 10 o'clock to the Salpêtrière Hospital at the other end of the city A pleasant way to reach the hospital, however, is to take one of the flying little propellors on the river and after a delightful sail past many ancient and modern landmarks, to land at the Pont d Austerlitz A few steps along the broad but not particularly elegant Boulevard de l'Hôpital will bring one in front of an old-fashioned building over the doorway of which will be seen engraved the words, *Hospice de la Vieillesse Femmes* Not far away rises the vast Halle aux Vins, which would presumably charm into ecstasies our bibulous friends, near by are the famous Jardin des Plantes, especially interesting to medical men as having been founded by Richelieu at the suggestion and solicitation of Labrosse, physician to Louis XIII How much more influential medical men have been and are to-day in the history and government of France than they are in America Why?

The Salpêtriere, named after a large saltpetre manufactory that was once in the vicinity, is said to be the largest almshouse in the world It consists of an irregular assemblage of buildings with surrounding gardens, courts and promenades, all covering an area of about seventy-four acres A brick wall surrounds the whole Altogether the various buildings comprise forty-five large blocks These are lighted by more than five thousand five hundred windows Louis XIII began building the institution as an arsenal, afterward using it to relieve Paris of the numerous beggars produced by his wars It was also used as a kind of general hospital Additional constructions were added to it at various times Louis XIV conferred upon it a large grant of lands and under this monarch its main building was erected after the designs of Liberal Bruant, the architect of the "Invalides" The most interesting architectural feature is the church built in the form of a Greek cross in the center of the grounds, and containing a fine altar, dating from 1670, beneath the center of the large octagonal dome Many of the main buildings are arranged in parallel lines with an archway beneath connecting the intervening courtyards The first of these buildings that one comes to after entering the gateway is the *Bâtiment Mazarin* built by the cardinal of that name for the aged and infirm women, who during their youth were servants in the establishment Their lodging was given to them gratuitously, they were allowed the same food they had been accustomed to as servants and which was better than that given to the paupers, but they were paid no wages In one of the yards with graveled walks and shady trees stood about a dozen brick buildings with overhanging roofs after the style of the Swiss chalets Each interior was a single apartment about fourteen feet square and was for the accommodation of a special *class* of insane The Salpêtrière is devoted to the care of the aged infirm, the insane, the epileptics, the idiots and the defective children The hospital proper was a detached building of three stories and an attic, and contained twenty-four "*salles des malades*" The "*salle aux bains*" is arranged in the "*rotunde*" with sixteen baths, each being surrounded with a white curtain and abundantly heated In 1850 a central workshop was organized for manufacturing and repairing, for destroying old linen and bedclothes and for preparing lint for dressings, etc There are shops for carpenters, joiners and carriage makers The wash-house built on an immense scale bleaches every year, it is said, 1,500 000 pieces of linen, not only for the hospital but also for the Hotel Dieu, the Charity and the Hôpital des Cliniques All except the insane department is open daily for visitors The inmates have special days upon which they may receive their friends On Sundays and fête days they may wear whatever clothing their fancy dictates but on other days the costume of the hospital blue in summer and gray in winter, must be donned There are entertainments, including music and dancing, arranged for the inmates. The cooking for the whole establishment is done in one immense kitchen. The insane of course eat in their own special dining room. The individual allowance consists of 10 decagrams of bread, 13 decagrams of meat, 45 centilitres of bouillon, a dish of vegetables, some dessert and 12 centilitres of wine. As for the insane department, the asylum is of course a very old one but its management is quite in accord with the most modern requirements. It will always be interesting on account of its association with the great reformer Pinel, a large and magnificent painting of whom striking off the chains of the grateful patients, hangs over the platform in the room in which Charcot held his public clinics.

In 1662 the institution contained nearly 10,000 people. During the Revolution the number of indigent females, the males being always sent to the companion institution the Bicêtre hospice out on the road toward Fontainebleau, was 7,000 or 8,000. Since that time the population has been steadily reduced and the management correspondingly improved. Statistics in regard to the number of inmates are obviously subject to much variation. In 1889 the total population consisted of about 6,311 souls, of these 590 were of unsound mind.

In passing it may be of interest to state that the Hospice de Bicêtre, named from John, Bishop of Winchester, Bichestre, Bicestre or Bicêtre, was founded by Richelieu in 1632 for retired soldiers. It is a most ungainly looking structure and resembles more an impregnable fortress than a hospital. It is for men what the Salpêtrière is for women, and with its rich clinic material Dejerine and others are doing some splendid work. The guillotine was first started in its deadly career here and within its walls Victor Hugo has placed the scene of his powerful story *Le Dernier Jour d' un Condamné*.

Much to my regret so much space has been already occupied that I can do but little more than mention the clinics of Professor Charcot. Having been the fortunate recipient of an autograph invitation to the home and public and private clinics of this great man, I had somewhat in my sketchbook that might have proved of interest. His uniform courtesy and kindliness, his warm feeling for America and Americans his enthusiasm and sincerity, his immense learning and clearness in imparting knowledge, his marvelous tact, gentility and preciseness could have elicited only praise from anyone who happened to know him, let alone from one who was his warm admirer. It is no wonder that, when he was gone, his great scientific attainments and his charming personality made it difficult for the authorities to fill his place. The story of his life, which has been often told, is a standing encouragement to every ambitious young doctor of slender means. Work, hard conscientious work, seems to have been its guiding motto.

Professor Charcot held his public clinics in a special hall at the Salpêtrière every Tuesday and Friday morning from 9 to 12 o'clock. Occasionally he would be delayed until near 10 o'clock. The hall was a long narrow room, lighted by small, square old-fashioned windows, with a large platform at one end and an ascending row of benches for the students. Over the platform hung the large painting of Pinel. On the platform were a long table for the use of his private pupils and assistants, and a series of high back benches for invited guests and the patients to be presented to the class. Aside from a loud ticking clock over one of the doors, the walls were devoid of every sort of ornament. From a small door leading out from an anteroom, we would follow the professor on to the platform, making a goodly sized procession of assistants, secretaries, students, guests, visitors and patients. The class upon the audience benches consisted of about one hundred and fifty men and women, intent, studious and ready with note books to take down the first words uttered by the lecturer. The professor always wore a small, tight-fitting scull-cap and remained sitting during the entire discourse. His style was smooth, regular and systematic, resembling a memorized sermon, and showing a calm, complete mastery of the subject in hand. Rarely, he would get up to make some examination himself upon a patient or indicate some point he was impressing upon a diagram. Usually his assistant, Gilles de la Tourette, would do that for him. He used very few gestures and generally would keep his gaze fixed upon the back of the room over the heads of the students, as though he were in a sort of reverie. He rarely attempted any humor, and when it did arise it usually had its origin in the patients or something apart from the speaker himself. Whenever he was lecturing upon any one special disease, he would line up a number of patients, as many as twelve or fifteen sometimes, upon the platform. If it were necessary he would insist upon their divesting themselves of every stitch of clothing, so that as some one said, they looked like a row of innocent Fiji Islanders. Rarely, if ever, did he put the women to this wholesome exposure. When the hour of noon arrived, a large gong would sound, the last sentence would be completed and in a quiet, methodic way the professor would suddenly rise and vanish through the side door.

In his daily private clinics, in a small room before half a dozen or more pupils, he would appear less methodic and showed more of his natural disposition toward friendship and personal intimacy. Here all kinds of cases would be examined, discussed and minutely studied. To observe him make a differential diagnosis, as for instance, between hysteria and syringomyelia in a man without a clear history, was a treat in close logic and correct inference. The French nation are reputed to be a neurotic people. At all events they present to the science of medicine a goodly amount of psychosis and neurosis for study. Happy was it that so calm, industrious, logical and dispassionate an observer as Charcot arose and studied amongst them. The debt which not only neurology but the whole of medicine owes to this master can never be repaid and will probably scarcely ever be equaled by another.

THE EVIDENCE OF INSANITY, AN OUTLINE

BY J. SANDERSON CHRISTISON, M.D.

CHICAGO, ILL.

GENERAL CONSIDERATIONS

The whole question of insanity hinges on the *origin*, the *support* and the *display* of ideas. Its pathology has nothing distinctly characteristic, being merely a measure of functional incompetence whatever the coexistent facts. But as all motion is potential in ideas, ideation has its equivalent in molecular change and thus mental aberration has its physiologic concomitants.

No mortal can be said to be free from errors of fact or opinion of one kind or another, but comparatively few resist demonstration—logical, or objective refutation An idea that does not fit with popular belief is not necessarily a delusion Indeed, if it does not clash with any demonstrable principle or particular fact, it can not be regarded as a delusion, for we have no other means of proving it false than by such evidence It may be an intuitive prophecy or the product of a genius The grand steps of civilization were often due to conceptions which at their birth were commonly regarded as "off" or insane, and it is quite in keeping with the order of things that exceptionally profound minds should discover truths beyond the ken of contemporaneous comprehension The common mind the non-meditative, is so much a product of our political, educational and social machinery that comparatively few think deep enough to think much differently, and the machine-made creature or social puppet is regarded as quite sane though he may hold all the delusions agoing, which by and by are exploded by what he may call a "crank "

The higher walks of life are hardly freer from delusions than are the lower, to-wit Only a few years ago the so called Darwinian theory of evolution became epidemic in certain learned circles although based on absolutely nothing but circumstantial evidence Since then many of its votaries have so qualified the theory that it has lost its original peculiarity of something from nothing, and now it stands for little more than the progress of a plan as yet too feebly perceived to reveal much of origin and purpose, but disclosing the immutability of entities (characteristic or essential powers) by which chaos is precluded and progress assured What is potential in plan must be specific and definite in form, and can never intrinsically be less or more in essential characteristics One word more on this point Laws of nature are said to be immutable, they must be, or chaos would result But laws are not separable from things (entities), they are identical with their properties, therefore specific entities are immutable Again, specific entities must be created, not evolved (form and activity are conditioned by environment and have reference to growth and chemic union) They can not lose their intrinsic (specific) qualities unless we say it is a law that laws are not necessarily immutable, which is a *reductio ad absurdum* Evolution is extension not addition I am not writing to prove the delusional nature of Darwin's hypothesis, which by some has been accepted as an established fact But the logical results of a truth are not acts of insanity Some twenty years ago when the theory was dominant, and while its sister delusion "spontaneous generation" also had a spurt, a young Englishman, while out of employment and discouraged, suicided by jumping from a river bridge He left a note stating "man is but a monkey, so I didn't care to live" This was not an accurate statement of Darwin's idea, but it contained the popular notion having a fatalistic principle What is the criterion for this suicide's act? Was the act that of insanity, or was it a logical result of prospects, both immediate and remote, in the light of the existing conditions?

But the history of civilization is full of popular delusions varying and vacillating, and sometimes violently active They were originated as they also now are, by circumstantial evidence, a form of suggestion, and prevailing by virtue of a common fitness, a common degeneracy The familiar biblical expression, "my sheep ' implies both the idea of enfeeblement and the need of a leadership to overcome the prevailing delusions and conditions therefrom It applies now as then, for just as water can not rise above its own level, so the individual mind can not transcend its own powers of comprehension without extrinsic aid He needs the stimulus of a reinforcement, coördinate with cosmic plan It is a curious fact that in spite of the self-evident truth of our absolute dependence, we almost totally ignore it, and by our acts imply that the world was made wrong This is the root of criminality, which is the remote or immediate background of all insanities, and moral palsies—their last analysis

Definition of Insanity—A delusional state of mind fixed against reason By this I mean that a delusion exists either manifest, subconscious or latent, just as any idea may be, and that neither the logic of facts nor objective evidence are effectual to dissolve It applies equally to fleeting and fixed delusions Reason is futile for dissolution, although it may sometimes have a subduing or eclipsing effect for a time more or less brief This state is due to such a degree of brain inefficiency, that the energy production is inadequate for the attention required for a complete conception of the situation By a manifest delusion I mean a delusion so dominant that most of the subject's conduct is regulated by it, by a subconscious delusion I mean a delusion which is not manifest unless elicited by inquiry, by a latent delusion I mean a delusion which practically does not exist in definite form, but has existed, and although inquiry may only elicit a denial, certain circumstances may evolve it and in a violent manner, as in some forms of epilepsy and recurrent mania Such cases are both the most dangerous and most difficult to pass upon

Character of Delusions—A delusion is an idea which is incorrect in time or in place, or is non-existent in fact It becomes an insane delusion by virtue of its fixity against reason—the futility of argument

Origin—Insane delusions have three origins 1, delusions due to more or less remotely acquired errors of perception and with present mental incompetency—centric delusions, 2, delusions due to perceptive perversions of sensation arising within the nervous system, and with present mental incompetency—hallucinations, 3, delusions due to perceptive perversions of sensation arising at the periphery or end organs, and with present mental incompetency—illusions All three forms involve perception, reason and will

Support—1 An insane delusion may be more or less plausible by virtue of circumstantial evidence, as when some of the factors are truths, as is sometimes the case in delusions of conspiracy to deprive of property or personal liberty 2 An insane delusion may be monstrous, by containing a claim against all evidence or possibility, such as a claim to be the "mother of God" or a "horse" In my opinion many such delusions are not real, but sportive, as their subjects' conduct is commonly very inconsistent with the delusions

Display—1 An insane delusion may be, *a*, active or directly manifest and unreserved *b*, subconscious or indirectly manifest and reserved *c*, latent, as in lucid intervals, when it has no formal existence 2 They may be *a*, persistent, *b*, c [illegible] bl [illegible] urrent 3 They may be of *a*, gran [illegible] ower rank, form, etc , *b*, persecution, as of poisoning, torture, defamation, etc , *c*, debasement, as of personal vileness or incompetence, etc , 4 They may exist with *a*, excitement, *b*, depression, *c*, composure

The more centric physiologic concomitants of insanity are indicated by the degree of promptness, pertinence, distinctness, fluency and coherence of speech

The other physiologic concomitants, which may or may not be present, are tremors, palsies, incoördinate muscular movements, sensory defects, nutritional changes and emunctory irregularities in addition to the purely psychic phenomena

It may be stated as a rule that the less the physiologic concomitants are manifested the more obstinate the insanity, because the more insidious and subtle is the centric (cortical) defect It also may be said that as a rule hallucinations with insanity indicate the worst prognosis owing to their being due to a more gross physiologic disturbance of centric areas than are purely centric delusions, and which when they do not speedily recover, generally result in a more serious and permanent damage to the brain Illusions being due to peripheral perversions are as a rule the least serious indications

Whatever of abnormal mind is not included in my definition of insanity will come under the headings of moral palsy and criminalty

Definition of moral Paresis —A defective power of inhibition (will) to such an extent that although the subject may know a particular act is wrong, he is unable to refrain from doing it under special exciting circumstances or provocation It is due to a defective action of the brain which may be caused by cranial injury, shock, fever, poisoning, inherited fault, habits of dissipation of one kind or another, etc It includes some cases of inebriety, neurasthenias (hysteria, hypochondria, etc), fad manias (fanaticism), violent temper, vagrancies, prostitution, etc

Definition of Criminality —A disposition of conduct n which selfness is the ruling principle existing with the power of discernment and the power of choice It is due to a denial or eclipse of first principles The incentives are position, wealth and pleasure to be obtained at the expense of truth, justice and economy when in conflict with purpose There is a total absence of fraternal love in the humanitarian sense

In criminality there is a delusional origin in reference to First Principles, and is therefore constitutional Education is the remedy In insanity the delusional state is incidental to a pathologic cerebration, and can only be remedied by physiologic means The remedy for moral palsy is chiefly discipline

THE STATISTIC EVIDENCES OF THE VALUE OF VACCINATION TO THE HUMAN RACE, PAST, PRESENT AND FUTURE

Read before the American Medical Association at the Jenner Centennial Celebration held at Atlanta Ga May 1896

BY EUGENE FOSTER, M D

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE AND STATE MEDICINE AND DEAN OF THE FACULTY OF THE MEDICAL DEPARTMENT UNIVERSITY OF GEORGIA, AUGUSTA GA

(*Continued from page 677*)

PROPOSITION 5

Notwithstanding a marked decrease has occurred in the total smallpox death rate, a still greater decrease has taken place in the smallpox death rate among children

From the mass of statistics at hand to demonstrate this proposition I select the evidence relative to the value of vaccination as shown by the enforcement of the compulsory laws of Great Britain

In reckoning the success or failure of compulsory vaccination in Great Britain, we must remember that the law was enacted to protect helpless children from the fatal consequences to themselves of obduracy or carelessness of the parent in failing to protect them from smallpox by having them vaccinated Let us take this epidemic of 1870-73, which has afforded vaccinophobists such an arsenal of facts to prove the worthlessness of vaccination, and see if in enacting compulsory vaccination laws the State exercised a wise and prudential care of its infantile population Prior to the enactment of compulsory vaccination laws, 70 to 80 per cent of the annual smallpox mortality of Great Britain was among children under 5 years old What has been the average annual mortality in this class since compulsory vaccination? Take England first The law requires vaccination of children at three months of age The compulsory vaccination law of 1853 was very defective in that the machinery provided for registration of births, and vaccinations thereafter, was not such as to enable the authorities to know and secure the vaccination of all the children falling within the provisions of the law Defective as it was in this respect, it yet had a salutary effect, for the vaccinations among this class were more than doubled over the same period anterior to the enactment of the law It must be admitted that this result was largely due to the knowledge of parents that if they failed to comply they laid themselves liable to a penalty for such neglect In a few years we see the annual smallpox death rate reduced to 55 per cent of the total mortality from this disease Fifty five per cent remained the average annual mortality in this class until the laws of 1867 and 1871 were enacted By the law of 1867 a full and proper system for registering compliances with the compulsory law was inaugurated Boards of Guardians throughout the kingdom were authorized by law to compel such compliances, and were given full authority to appoint officers whose duty should be to rigidly inquire into all failures to comply with the law When such persons were found, these officers should warn the delinquents to comply with the law within a specified time, and if such persons failed to heed the warning the officers were to institute legal proceedings to require compliance By the act of 1871 Boards of Guardians were required to appoint such officers The epidemic of small pox commenced in the latter part of 1870, and we are told that "only a portion of the population in England under 5 years of age was within the operation of the act of 1867 During the continuance of the epidemic a larger proportion came under its provisions, and some came also under the provisions of the act of 1871 The result was manifested in a reduction of the proportionate smallpox mortality under 5 years of age from 55 per cent of the entire mortality from that cause to 33 5 per cent in 1871, and to 30 per cent in 1872 The act of 1867, being in some of its most important requirements permissive only, had been carried out with various degrees of efficiency by different local authorities In those places in which the action taken under it had been tardy and ineffective, the mortality in young children amounted to or approached its old proportions, in those places in which such action had been commenced immediately on the act coming into operation, and been steadily continued, a remarkable diminution in that proportion was observed " [94]

LONDON

Anti vaccinists gleefully ask How about the smallpox death rate of London in 1870-73? Let us examine into the matter For twenty years prior to 1871, when the authorities provided gratuitous vaccination, but when compulsion was really nominal, the smallpox death rate of children under 5 years of age was more than 50 per cent of the total smallpox death rate From 1851-60 it was 59 5 per cent , and from 1861-70 it was 54 3 In 1871 and 1872, notwithstanding the negligence of the authorities of some of the unions in relation to enforcing vaccination, the average annual smallpox death rate of children under 5 years of age to the total of smallpox mortality was 36 7 In the epidemic of 1881 children under 5 years of age contributed only 27 8 per cent of the total smallpox mortality of London [95] In 1872, in Great Britain, only 85 per cent of the births were certified as successfully vaccinated Deducting the percentage of children having died before being vaccinated, the percentage vaccinated to the total births living was 94 per cent certified as successfully vaccinated

SCOTLAND

How about Scotland? Mr P A Taylor makes himself happy over the failures of compulsory vaccination in Scotland Upon what is his opinion based? Let us see Here is a fair test, for the compulsory vaccination law of Scotland was enacted Jan 1, 1864, and from that date to Dec 31, 1871, the report of the registrar general for Scotland states, that after a deduction had been made of all children who had died before they could be vaccinated, 96 5 per cent of all children alive were certified as having been successfully vaccinated One per cent was certified as being in such health as to prevent vaccination or having been repeatedly tried and found insusceptible, and 2 5 per cent unaccounted for on the registers From this it appears that the children in Scotland under 7 years of age were protected by vaccination to a remarkable degree But, as has been well said, "it is equally obvious that the whole infantile population can not be universally vaccinated, nor constitute a class among whom if smallpox prevail in the country there could be any reasonable expectation of meeting with complete exemption from that disease, for it includes, 1 all who are under the age by which vaccination is enforceable, of whom, of course a very large proportion would remain unvaccinated , 2, not a few somewhat above that age are still remaining unvaccinated from the carelessness of their parents in neglecting to have vaccination done till they had received legal notice of warning and risking it probably for some time after that, 3 children in whom there was postponement of vaccination on account of their state of health , and 4, many doubtless still unprotected among the cases which had appeared in each year s return as 'postponed,' 'insusceptible,' or 'unaccounted for' Now, as there are nearly 120 000 children born in Scotland each year who until they are 6 months old do not come under the operation of the law , as there are about 1,000 of each year s births carried on as 'postponed' or 'insusceptible' , and as there are about 2,500 annually respecting whom nothing is known it is quite certain that there must always at any given time be among the young population of Scotland extremely well protected as it is on the whole, a considerable actual number of unvaccinated children "

---

[94] Dr Seaton's Report in Report of Medical Officer of Privy Council 1874

[95] Eleventh Annual Report of Medical Officer of the Local Government Board

Now for the results of this unprecedented vaccination in a community of civilians From year to year, prior to compulsory vaccination, the average annual smallpox mortality in children under 5 years of age amounted to 74 per cent of the total smallpox mortality in Scotland To fairly test the prophylaxis afforded by compulsory vaccination, we must take the children under 7 years of age, the epidemic having begun in 1871 The returns of the registrar general are only divided as follows Those under 5 years of age 5 to 20, 20 to 60, and those above 60 years of age We therefore take those under 5 years of age, they being only those which can be used to test the value of compulsory vaccination From the enactments of the compulsory law in 1864, the mortality of this class steadily declined from 74 per cent of the total smallpox mortality, until in the epidemic of 1871 it was for the whole of Scotland just 21 4 of the total smallpox mortality The mortality for the whole of Scotland had not been ascertained when Dr Seaton (from whose reports these data are extracted) rendered his report in 1874 But let us take the eight principal towns of Scotland, from which to derive further information on the subject

SMALLPOX DEATHS IN THE PRINCIPAL TOWNS OF SCOTLAND

Year	At all ages	Under 5 years of age	Deaths under 5 years of age per cent of total deaths
1871	886	195	22 0
1872	1,537	362	23 5
1873	467	124	26 5
1874 to June inclusive	302	69	22 8
Total, 3½ years	3 192	750	23 5

Well may the registrar general, in his report for 1872, say in his comments on that year— 'If the same relative mortality had taken place in children at that age (under 5 years) as occurred during the previous epidemics, when they were less efficiently protected by vaccination instead of only 362 children under 5 years of age having died from smallpox in the eight towns during 1872 3,370 would have died The enforcement of the vaccination act therefore during the seven previous years, appears to have had the effect in those eight towns alone, of saving the lives of upward of 3 000 children " So much for the direct proof from the history of Scotland as to the beneficent effect of compulsory vaccination Now let us compare the relative mortality of children under 5 years of age in Scotland with other countries A glance at the following table will show the superior effects of the law of Scotland

SEATON'S REPORT, 1874

Towns, or groups of towns, compared	Actual smallpox deaths under 5 years of age during the whole period of the epidemic in each town or group of towns	Smallpox deaths under 5 years of age during the whole period of the epidemic for equivalent population of 1 000 000 of all ages
Eight principal towns of Scotland (population 1,083,750), 1871–74	750	692
Berlin (population 882,569), 1871–72	2 837	3 448
Hamburg (population 338 974) 1871–72	1 938	5 717
Leipsic (population 106 925) 1871	659	6 200
Eight principal towns of Holland (population 693 080) 1870–72	4,474	6 445

Compare next the smallpox mortality under 5 years of age with the population living under that age, respectively, in the various towns or groups of towns [76]

Towns or groups of towns compared	Population living under 5 years of age	Smallpox deaths under 5 years old during entire period of the epidemic in each place	Smallpox deaths under 5 years of age during whole time of epidemic for equivalent of populations of 100 000 children under that age
Chief towns of Scotland (3½ yrs)	147,483	750	508
Berlin (2 years)	88 093	2,837	3 200
Leipsic (1 year)	8,545	65	7 712

These are the only towns in which the data for this last table were at hand for comparison when the table was formed in 1874 Assuredly there must be some patent reason for this variable death rate of infantile populations in the countries having compulsory vaccination laws Let us try and find it A brief review of the law, together with the manner of its enforcement in the respective places, will perhaps enable us to solve the problem

1 *Scotland* —We have just seen the wonderful utility of compulsory vaccination in Scotland in comparison with the other countries specified in the tables just given The law is stringently enforced, and the machinery therefor is complete, as evidenced by a vaccinated population under 5 years of age of 96½ per cent

2 *Berlin* —In Berlin the law required that all children should be vaccinated at one year of age No penalty however, was attached to neglect to comply with the law, unless smallpox follows such neglect The delinquents were rarely prosecuted, and a good proportion failed to have their children vaccinated until they attained school age All children seeking admittance to the public schools had to present a certificate of successful vaccination before being received therein Dr Guttstadt in 1873 attributed the high mortality in Berlin in the epidemic (1871 1872) to a large accumulated number of children, whose parents had failed to have them vaccinated at 1 year of age, as required by law

3 *Hamburg* —There was not at the time of the outbreak of the epidemic any compulsory law, and no means to prevent parents from neglecting to have their children vaccinated, except a law which required all children applying for places in the public schools to produce a certificate of successful vaccination Therefore it was common to find children who had attained 2 years of age, and often 7 or 8 years before vaccination was attempted This large residuum of unvaccinated children is sufficient to account for the greater prevalence of smallpox in Hamburg than in those of Scotland

4 *Leipsic* ⎱ The same was substantially true of these as in
5 *Holland* ⎰ Hamburg

IRELAND

What of compulsory vaccination in this country? triumphantly ask the anti vaccinists Let us test it first upon the children under 5 years of age, the class whom primarily the law was intended to protect The compulsory vaccination act of Ireland came of force Jan 1, 1864 The machinery for registration of compliances with the law as well as the lack of officers to warn delinquent parents whose children remained unvaccinated beyond the prescribed age (six months) and to take the necessary steps to enforce compliance with the law shows the act to b   defective than that   nd

By the   ublic vaccina   local govern

---

[76] Seat

ment board of Ireland, compared with the register of births from 1865 to 1872 inclusive, it is shown that 81 per cent of the births were vaccinated by the public vaccinators (The public vaccinators do almost the entire vaccinations in Ireland, except in the large towns) In Scotland the percentage of these vaccinations has been shown to be 96½ of every 100 births We therefore see that in Ireland there is always a very large residuum of unvaccinated children, there being in 1872 33,440 children who were not vaccinated until they had attained one year of age In 1873 there were 19,258 such cases Let us now compare the smallpox death rate of this class with the total smallpox mortality of the periods anterior and subsequent to the compulsory act Seventy nine per cent of the total smallpox mortality of Ireland was in children under 5 years of age, as shown in the report of the epidemiological society in 1853 Under the medical charities act, and the act of 1858, the public vaccinators had been enabled to reduce this percentage to 75 By the operation of the compulsory vaccination act, in 1865 and 1866, the percentage of this class of deaths was reduced to 50 From 1866 to 1871 smallpox was almost wholly absent from Ireland When the epidemic of smallpox began in 1871, it found the children under 7 years of old remarkably well vaccinated, and as a consequence we find the percentage of deaths in this class as follows 1871, 20 5, and in 1872, 25 per cent of the total smallpox mortality

Now let us take Dublin, one of the cities especially pointed out by anti vaccinists as an illustration of the utter failure of compulsory vaccination In Dublin, in the two years in which the epidemic prevailed, there were 1,557 deaths from smallpox Of this number 362, or 23 per cent, were in children under 5 years old Dr Seaton was unable to give the proportion which these 362 deaths bear to the total population living under 5 years of age But he shows the comparative mortality to the whole population of Dublin, and contrasts these with the following places The deaths under 5 years of age per million of living population in each place were as follows

Dublin,	1 150
Eight principal towns of Scotland,	692
Dundee,	1 584
Berlin	3 448
Hamburg,	5 717
Leipsic	6 200
Chief towns of Holland	6 455

Let us see what has been the result of compulsory vaccination upon the whole population of Ireland From the census taken in 1841 it was shown that for the previous ten years smallpox was the second most fatal disease in Ireland The deaths in that period of time were 58,000 When the census was taken in 1851 it was found to be the third most fatal disease For nineteen years previous to the act of 1863, the average annual mortality from smallpox was, as shown in the twenty first annual report of the poor law commissioners for Ireland, 2,640 The compulsory vaccination act of 1863 came of force at the time of decline of a considerable epidemic During the first year, which, it must be admitted, was too soon to be fairly claimed as wholly consequent upon the operation of the act, the deaths from smallpox were 854 From 1865 to 1870 inclusive, the smallpox mortality had fallen to such an extent as to be without precedent in the history of Ireland, being for the six years respectively 347, 180, 20, 19, 20 and 32 In the epidemic of 1871-1872, the deaths from smallpox were 665 in 1871, and 3,248 in 1872 Now let us compare the smallpox mortality of Ireland previous and subsequent to compulsory vaccination, and see what will be the result of the investigation For nineteen years previous to the compulsory vaccination the average annual deaths from smallpox were 2,624, for ten years subsequent to compulsory vaccination the annual smallpox deaths were 583 [7] Therefore we see that under compulsory vaccination for the ten years of its operation, as compared with the nineteen years anterior to it, the deaths were not a fourth of those in the non compulsory period

Propositon 6

In every epidemic of smallpox, the unvaccinated portion of the population has, without a single exception, shown a vastly greater proportional attack rate as well as death rate from smallpox relative to their numbers than the vaccinated

STATISTICS PROVING THIS PROPOSITION

In a severe epidemic of smallpox which prevailed at Norwich im 1819, Mr Cross minutely observed 112 families, in all of which there were cases of the disease, and the annexed table shows the result Among 215 persons unprotected by vaccination there were 200 cases of smallpox, and of these forty six proved fatal, while among ninety one vaccinated persons the only effects of this terrible infection were 1, that one girl, who had been vaccinated nine years, "had a mild disease, limited to twenty pocks, and lasted only six days before it began to decline," and 2, that another, who had been vaccinated five years, went through "the disease in half the time (of her unvaccinated sister) without danger or detriment, a few very minute pits upon the tip of the nose being the only permanent traces "

	Number	Cases of Smallpox	Deaths by Smallpox
Total number of persons in the 112 infected households	603	202	46
1 Protected by previous smallpox [8]	207		
2 Protected by vaccination	91	2	
3 Unprotected	215	200	46

By reference to the following table, it will be seen that, in a number of places observed, the death rate varies among the vaccinated from an inappreciably small mortality to 12½ per cent, that amongst the unprotected, it ranges from 14½ to 53 8 per cent

Death rate per 100 cases [9]

Places and times of observation	Total No of cases observed	Among the unprotected	Among the vaccinated
France, 1816-41	16 307	13 12	1
Quebec 1819-20		27	1 66

Epidemiological Society return no date	4 624	19 7	2 9

Compare the relative death rates from smallpox in London in the epidemic of smallpox for the year ending May 29, 1881, between the vaccinated and unvaccinated Here is the table taken from the Eleventh Annual Report of the Local Government Board, 1881-82

Death rate of people of subjoined ages	Per 1 000,000 of each age of the vaccinated class	Per 1 000 000 of each age of the unvaccinated class
All ages	90	3 350
Under 20 years	61	4 520
Under 5 years	10 5	5 950

Table D—Number of deaths and vaccinational condition of those being over 3 months and under 10 years of age who died from smallpox in England and Wales 1881-87

Vaccinational condition	Deaths 1881-87
Vaccinated	145
Unvaccinated	1 427
No statement	1 402
Total	2 974

Note—The unvaccinated are 90 8 per cent of those as to whose vaccinational condition there was information and 48 per cent of the whole

---

[7] See Seaton s Report 1874

[8] Mr Cross mentions that he met with several who were supposed to have had smallpox formerly, yet (p 15) notwithstanding took it on this occasion but he does not state whether such cases are included in the above summary In this epidemic the vaccinated slept in the same rooms, and in some instances in the same beds, with those having smallpox So also (as quoted by Steinbrenner) in Copenhagen—of 650 vaccinated persons who suffered in the variolous epidemics 1823-27 only 5 died, being at the rate of 1 in 132 while of 176 unvaccinated persons who contracted the disease more than a fourth seems to have died, and of 153 others, who professed previously to have had smallpox there died 31 And similarly in the epidemic of 1828-30, and part of that of 1832-37 it seems that out of 228 unprotected patients 63 had died but of 1 373 cases of post vaccinal smallpox only 11 were fatal

[9] Brit and For Med Chir Rev, October, 1857

TABLE I —Proportion of deaths under and over 15 years of age per 1,000 deaths from smallpox in vaccinated and unvaccinated persons respectively, 1881-87 (excluding deaths under 3 months)

Age	Unvaccinated	Vaccinated
Three months and under 15 years	597	126
Fifteen years and upward	103	874
Total	1,000	1 000

TABLE II —Statistics of the smallpox epidemic in Chemnitz in 1870-71 (See 2d Report Royal Vaccination Commission of Great Britain 1890 page 236 Zeitschrift des Konigl Preuss Stat Bureau Jahrgang 12 1872 Art Die Pocken Epidemic in Berlin 1870-72 by D Guttstadt)

NOTE —Dr Max Schultz writing of Flinzer s statistics calls attention to the fact that they show there was 1 case of smallpox to every 255 households containing none but vaccinated persons but 1 to every 26 households containing both vaccinated and unvaccinated persons The figures prove the danger which unvaccinated persons are to the vaccinated and thereby establish the value of compulsory vaccination Vide Impfung Impfgeschaft etc Berlin 1888

Deaths —Of 3 596 cases 249 or 6 92 died Among the deaths are those of 117 boys 17 male adults 111 girls and 11 female adults All the children who died were unvaccinated, and of the adults 3 males and 4 females were vaccinated the remainder unvaccinated

Of the 249 deaths 242 were thus unvaccinated and only 7 of those vaccinated the former category contributing 97 19 and the latter 2 81 per cent of the deaths Separating the cases of smallpox among the vaccinated from those among the unvaccinated persons, we find that of the former only 0 73 per cent died, but that of the latter class 9 16 per cent died

Of the 221 cases in the town hospital 181 had been vaccinated 37 were unvaccinated and 3 were doubtful None of the vaccinated died but 11 of the unvaccinated succumbed to the disease (15 cases of unvaccinated children under 10)

Hence the accuracy of the following table given by Lotz on p 56 of his 'Pocken und Vaccination

Age	Vaccinated			Unvaccinated		
	Cases	Deaths	Mortality Per cent	Cases	Deaths	Mortality Per cent
For the 1st year	8			373	102	27 3
For the 2d year	15			528	51	9 6
For the 3d year	0			444	26	5 9
For the 4th year	1			331	29	6 3
For the 5th year	43			222	9	4 0
For the 6th year	35			197	7	3 6
For the 7th year	46			105	1	0 9
For the 8th year	28			98	2	2 0
For the 9th year	18			71	1	1 4
For the 10th year	71			71		0 0
Total under 10 years of age	265			2 410	220	9 0

(To be continued)

SOCIETY PROCEEDINGS

The American Public Health Association

[Special Correspondence of the JOURNAL]

The Twenty fourth Annual Meeting of the American Public Health Association held at Buffalo, N Y, Sept 15-18, 1896

The Executive Committee, in which all the business, other than reports of committees and presentation of papers, is practically done, and which is composed of the five officers, six elected members and the thirteen surviving ex presidents, nine of whom were actually in attendance, met at 10 A M, September 14, and was in continuous session the greater part of the day, and during the intervals of the regular sessions throughout the week

Ellicott Square, in which the meeting of the Association was held, is a marvel of modern construction, occupying the entire block of ground, the value of the site alone being rated at $1,000,000, and the cost of the building, complete in all its appointments, having amounted to $2,350,000 more The dimensions of the edifice are 240 x 200 feet, with an interior court 110 x 70 feet in size, glass roofed and giving abundant light to the 600 offices, 16 large counting rooms and 40 stores, besides the quarters of the Ellicott Club, which occupies nearly the whole uppermost (tenth) floor, and the assembly rooms on the second, in which the Association held its meetings The principal room was gracefully and appropriately draped with the national flags of the United States of America, Dominion of Canada and Republic of Mexico, which countries are represented in the membership, but the abominable acoustics of the hall, due to the numerous intervening columns, and the medley of noises from the streets, make it a trying ordeal for the speakers to reach their distant auditors The extensive daily programs for morning, afternoon and evening sessions were carried out without failure, and the interest of the members in their work was shown by their persistent attention and regular attendance to the adjournment on Friday afternoon

The appointed hour found about two hundred and fifty persons on the floor, the adjoining offices of the Treasurer and Local Committee being crowded with members awaiting their turns to register The Mexican contingent numbered thirty four persons and that from the neighboring Dominion almost as many more A number of women were present, and as a daily paper later commented "The languare of some of the papers opened their eyes to the brusque directness with which scientific sanitarians deal with rather intimately personal problems "

The Association was called to order by the President, Dr EDUARDO LICEAGA of the City of Mexico, promptly at 10 o'clock, and the session opened with prayer by the Rev Dr Thomas R Slicer of Buffalo, after which the President called to the platform and introduced to the members the distinguished founder of the Association, Prof STEPHEN SMITH of the city of New York, and its first President during the years 1872, 1873 and 1874, after which time he declined reelection Dr Smith, after responding to the enthusiastic welcome which greeted him, disclaimed any special merit in the creation of the Association, which he declared to have been the logical outcome of the times, and paid generous tribute to his associates in the work, especially Dr ELISHA HARRIS of New York, who with himself bore the entire expense of the early meetings He also instanced Dr Joseph M Toner of Washington, D C, Dr Edwin M Snow of Providence, R I, Dr John H Rauch of Chicago, Ill, Dr Ezra M Hunt of Trenton, N J, and Dr Charles B White of New Orleans, La, the latter the first of the Presidents to die, although all the others mentioned, who successively occupied the presidential office, and were his earnest co workers from the beginning have subsequently died He extolled the wisdom of the Association in having adhered to the practice of placing its mere working business in the hands of the Executive Committee, and thus removing disputations and time consuming contentions from the floor of the general meeting, to the interference with its legitimate and more important labors While it has included some of the best men in the profession among its members, there were many others who were not medical, among them the Rev Dr Osgood, Dorman B Eaton, Commissioner of Education, and others This Association does not limit its influence to those in actual attendance at its meetings The larger audience outside of the Association give it its distinctive character He was especially gratified at the interesting feature of its development, which has made it eminently all American, through the extension of its membership to Canada and Mexico, and hoped that Cuba and the Central American republics might also become part of it This international association is all the more gratifying since experts in sanitary science are aware that no single country can protect itself, except so far as the English system obtains of making localities clean, instead of remaining apart and trying to fight epidemics A clean country is primarily a healthy one The Transactions of this Association, he was proud to say, have become an invaluable compendium of sanitary science, and Florence Nightingale wrote, years ago, that she could gather nowhere in Europe such information as was to be obtained in the reports and papers published by this body Perhaps the grandest work accomplished by the Association has been in the development and extension of State boards of health all over this Union—and it is very gratifying to see by the programs the prominent part taken by officers and members of State and provincial and municipal boards of health in its work

On the conclusion of ex President Smith's remarks, the Chairman of the Local Committee of Arrangements Dr ERNEST WENDE of Buffalo Commissioner of Health of that city, made the customary announcements of entertainments tendered the members and their families, which in accordance with the traditional practice of this Association, were only such as would not interfere with the purposes of its assembly The Local Committee had prepared a very attractive, both in typography and contents, souvenir brochure, edited by Dr WILLIAM WARREN POTTER Chairman of the Committee on Printing, containing well executed portraits and biographic sketches of the officers, lists of committees and other necessary information especially valuable for new members, and a novelty in the way of a membership badge, having a gilt buffalo surmounting and suspending by a tri-colored riband a gilt emblematic pendant. Each member was further supplied with a little book of detachable coupons, entitling those duly accredited to daily afternoon drives in tally-ho coaches, intended especially for wives and families during the attendance of their husbands and fathers at the sessions, and admitting to excursions and receptions—a most admirable provision against the intrusion, common to such occasions, of persons in no way interested in the Association as entertainers or participants.

The report of the Executive Committee was presented by the Secretary of the Association, Dr. Irving A. Watson, Secretary of the State Board of Health of New Hampshire, who performed this duty for the fourteenth successive annual occasion, making the usual announcement of the prospective business of the session, and reporting a communication from the Association of Master Plumbers of Canada, signed by their Secretary, J. C. Hughes, of Montreal, recommending the constitution of a committee on sanitation with special reference to drainage, plumbing and ventilation of public and private buildings, and such a special committee of five members was thereupon authorized. The Executive Committee further recommended the passage of a resolution, introduced by Dr. Samuel H. Durgin, Health Officer of the city of Boston, reviving the committee on disinfectants and disinfection, whose former report has been so many years the standard authority on these subjects, but which in view of recent experimental research and discoveries ought to be given the opportunity of including this later knowledge. The Secretary then reported the names of fifty-three new members, recommended by the Executive Committee for election, which was accordingly done by vote of the Association.

The eminently practical and expeditious manner in which this Association dispatches its routine and administrative business through its Executive Committee, permitted the legitimate work of the session to begin promptly at 10.45 a.m., with the "Report of the Committee on Car Sanitation," by Dr. Granville P. Conn, President of the State Board of Health of New Hampshire, Chairman. This report attributed much of the opposition of railway corporations to their disinclination to submit to the interference with their business and the expenses which the necessary charges required for their improved sanitation would involve. It spoke of bad ventilation of passenger coaches as worse than their overheating, denounced the objectionable practice of closing windows and locking doors after a trip, instead of throwing them wide open for thorough airing, and advocated the abrogation of the existing system of urinals. It backed the American railway employe against the world for disregard of passengers' comfort, and for habitual insolence nothing could equal the negro porter. It commended the *train de luxe* from Paris to Marseilles as an instance of what can be done to promote the health and comfort of travelers and wondered that any one who has had the opportunity of contrasting this service with the American system could hesitate to give credit where it belonged.

Two papers on the same subject followed: "Observations on the Cleaning of Railroad Passenger Cars," by Dr. Domingo Orvananos, of the City of Mexico, Secretary of the Superior Board of Health of the Republic of Mexico; "Possibilities of Contagion of Venereal Diseases in Railway Cars," by Dr. Tomas Noriega, delegate from the State of Chiapas, Mexico. The former advocated instead of the customary slipshod method of washing coaches that they should be carefully gone over with sponges saturated with a solution of mercuric bichlorid, that the coverings of seats and backs should be frequently changed and washed at every terminal station. Dr. Noriega narrated instances in his experience of purulent ophthalmias, unmistakably one to infection in Pullman car lavatories, resulting in total loss of vision of one or both eyes. He said that reform was necessary especially in beds, lavatories and water closets, and that in the latter, impermeable paper covers, to be removed after each visit, should replace the present permanent wooden seats. In the discussion which followed, Dr. Valentine of New York quoted the case of a bride, referred to him by another physician, who had contracted a specific ulcer on her lip by drinking from a public ice water cup, and said that in Antwerp he had seen fresh wooden covers supplied to each new occupant of a water closet. Dr. Kinyoun of the U. S. Marine Hospital Service, said that the hygiene laboratory of that service under his direction had been long engaged in investigating railway sanitation, and said that experiments were being made as to the proper disinfection of cars by subjecting all the several materials used in furnishing coaches to various processes. He suggested the inquiry as to the greater prevalence of cases of tuberculosis and diphtheria at the railway terminals and at the resorts for invalids affected with these diseases. He said the impure water supply in the railway service was responsible for many cases of diarrheal and enteric diseases, and declared that it was significant that the presidents and high officials of these companies do not drink the water they furnish to passengers.

The "Report of the Committee on Steamship and Steamboat Sanitation," by Dr. Frederick Montizambert, of Toronto, General Superintendent of Quarantines of the Dominion of Canada, Chairman, was then read. Dr. Montizambert said he had little to add to the reports made by the former Chairmen of the Committee, Dr. Durgin of Massachusetts, in 1891, and Dr. Gihon, U. S. Navy, in 1893, except to call attention to the proposed disinfection of ships by the electrolysis of sea water, a process actually in use by the French companies of the *Messageries Maritimes*. At the exhibition at Boulogne sur Mer, there was an automatic apparatus no larger than a coal scuttle, which could be connected with the ordinary electric plant by a couple of wires and was capable of producing three hundred liters of electrolyzed sea water per hour. The usual methods of disinfection, involving the employment of costly materials, were malodorous and left much to be desired.

Dr. Horlbeck, of Charleston, S. C., declared that enough had not been said about the wretched sanitary condition of our coastwise passenger steamships, and Dr. Gihon, U. S. N., described his present knowledge of the deplorable condition of the saloons of these vessels during their late autumn passages when crowded with consumptive invalids on their way to health resorts in Florida.

AFTERNOON SESSION.

The afternoon session began 3 p.m. with a paper on "The Composition and Infectiousness of Milk," by Dr. James F. Kennedy, of Des Moines, Iowa, Secretary of the State Board of Health of Iowa, and was an exhaustive inquiry into the relative mortality of breast fed children and those fed on milk, the latter being greatly in excess. He attributed a large proportion of the deaths to inanition from dilution with water, which is not only a fraud against the buyer but a crime against the children, who are literally starved to death. He narrated epidemics due to infected milk, which was a greater source of danger than dilution, and described the many ways by which morbific germs are introduced into milk—by washing pails with impure water, by the settling in pails and cans of dried germs floating in the polluted air of stable yards, by the unclean hands of milkers, and after reaching consumers by the filthy habits of occupants of insanitary houses. He declared the remedies to be inspection, cleanliness and sterilization.

The next paper on the program was "On Pure Milk," by Dr. Gardner T. Swarts, of Providence, R. I., Secretary of the State Board of Health of Rhode Island, who deplored the neglect of milk inspectors and physicians in his own State to ascertain the actual condition of the milk supply. He said that most of the enteritis of children was certainly due to filthy milk. He urged the establishment everywhere of milk farms similar to those near Buffalo, where the modus operandi of milking and delivering milk is carried out under the most healthful conditions and the purity of the milk certified by reputable physicians. The price of such milk must necessarily be higher, and it is only by educating the public that they can be made to pay the difference and to secure immunity from disease, which is more surely done in this way than by sterilization. There are people to-day who prefer dirty milk at four cents to good milk at eight.

The "Report of the Committee on Animal Diseases and Animal Food" was then read by Dr. D. E. Salmon, D.V.M., of Washington, D. C., Chief of the Bureau of Animal Industry, Department of Agriculture, Chairman, who, while describing how much had been done in the matter of animal diseases, said that the public still needed to be educated respecting them. Outbreaks of anthrax were undoubtedly becoming more frequent. While common in Europe, this disease had been rare here. The spores of the bacillus survive for years and are distributed through carelessness in the disposal of dead animals. The carcases should be saturated with coal oil and burned to ashes. Hides and wool are dangerous and even the hay from infected meadows used for packing crockery and glass. Tuberculosis is the subject of much attention on the part of the government, which, however, can only prevent the shipment of diseased cattle to other States, but has no control over its local sale. Tuberculous cows and swine are often found in the abattoirs, but there is necessity for cooperation between Federal and local inspectors. Some local firms insist on selling condemned carcases. The committee testifies to the amicable relations between the Bureau of Animal Industry and the

State Boards of Health, due largely to the influence of this Association An interesting part of the report dealt with rabies, which declared that while there was no need of alarming people, it was a duty to inform the public that such a disease does exist and is a menace to health and safety The Chairman had sometime ago to combat the theory that there was no such disease as Texas fever Is it reasonable to believe that a disease that has been described for two thousand years is a myth because a few physicians have never seen a case The committee has sufficient positive evidence to establish its existence and characteristics, and recommends the measures for reducing the number of worthless dogs be rigidly enforced, and that all others allowed to run at large be muzzled

This group of papers attracted great attention and provoked a very lively discussion Dr BAILHACHE while approving of the thorough supervision and inspection of dairies and dairy products recommended by Dr GARDNER T SWARTS, doubted its practicability Dr LEE of Philadelphia took issue with Dr KENNEDY respecting the sterilization of milk, in which he did not believe we had arrived at a sanitary ultimatum Since the practice two diseases have become prominent —infantile scurvy and rickets—which were not recognized when he studied medicine Fresh pure milk is better than sterilized, but he agreed if we are to cook milk at all we had better do it thoroughly Boiled milk is better than sterilized Dr HIBBERD of Indiana, ex President of the AMERICAN MEDICAL ASSOCIATION, questioned whether it had been established that any child had been diseased by milk from tuberculous cows, taken into its stomach He had never had a positive, indisputable reply to the question Can tubercle bacilli pass the digestive organs? He believed that sterilized milk starved children to death Dr LYMAN of Massachusetts said as it was possible for a child to be exposed to cold and not take cold, it was equally possible for it to live in a family where tuberculosis and similar diseases exist and not contract them He believed that the development of the general health by proper sanitary environments will be a better protection against disease than any special method of asepsis Dr CARTER of Des Moines, Iowa said it was a frightful fact that dairies are as a rule, filthy, that the cows are filthy and kept in filthy places and milked by men who are both filthy and diseased He had employed a man who had been previously employed for two years and when he saw that he did not wash his hands nor the cow's udder and remonstrated with him, he declared that he had never done so, and a second milker, who had also been working a year in a dairy, made the same admission He was opposed to muzzling dogs and thought a shot gun was a better protection against rabies Dr HOLTON of Brattleboro, Vt, agreed with Dr HIBBERD and said he had tried to find an undoubted case where tuberculosis had been communicated by the milk or flesh of the bovine race and had not found one He believed heredity, etc, accounted for the development of certain diseases He had for a year and a half without knowing it, drank milk from a tuberculous cow, subsequently discovered to be the worst in the herd He called attention to the danger from substituting patented food for milk

Dr KINYOUN and Dr SALMON controverted the statements of Drs HIBBERD and HOLTON that the infection of human beings by diseased animals had not been established When we consider that tuberculosis may be produced in animals by feeding them upon tuberculous tissues and find children die from tuberculous disease and know that the tubercle bacillus does penetrate the intestine, we are justified in inferring this as the source of their disease As to making children strong rather than destroy disease germs, it is the fact that the robust often die and the sickly do not Immunity does not depend on the strength of the individual We do not know how frequent this infection was twenty five years ago, and we would not know to day but for the tests that have been established How does Dr HOLTON know that the milk he drank was infected?

The next paper, "Contributions to the Study of the Pathogeny, Etiology and Prophylaxis of Typhus," by Dr FRANCISCO DE P BERNALDEZ, delegate from the State of Oaxaca, Mexico, was a very able presentation of the subject based on personal observations in many epidemics, and Dr Bernaldez's conclusions as to the limited contagiousness of this disease were accepted without discussion

The "Report of the Committee on Nomenclature and Forms of Statistics," by Dr SAMUEL W ABBOTT of Wakefield Mass Secretary of the State Board of Health of Massachusetts, Chairman, was read by Dr Walter Suiter of New York, particularized the latest changes in nomenclature by the College of Physicians of London, and was supplemented by a paper "On the Nomenclature of Diseases and Forms of Statistics," by Dr. EDUARD LICEAGA of the City of Mexico, President of the Association, and one "On Need of Uniformity in the Meaning of the term Stillborn," by Dr JESUS E MONJARAS of the City of San Luis Potosi, Mexico, Director of Hygiene of the State of San Luis Potosi

Dr LINDSLEY of New Haven, Conn, expressed his appreciation of the great importance of this series of papers There were a number of States which do not yet take sufficient interest in vital statistics, and as uniformity in nomenclature is the essential basis of an exact system of statistics, he hoped the Committee would be continued

The paper "On Dengue," by Dr HENRY D HORLBECK of Charleston, S C, Health Officer of Charleston, was an interesting account of the great epidemic of that disease at Charleston

A paper "On Municipal Responsibility for Healthy School houses," by Mrs ELLEN H RICHARDS, of the Institute of Technology, Boston Mass, was read by Dr Durgin, Health Officer of Boston, and one "On Woman in Preventive Medicine," by Mrs HARIETTA M PLUNKETT, President of House of Mercy Hospital, Pittsfield, Mass was read by title

EVENING SESSION

The evening session, to which the public was especially invited, was promptly called to order at 8 P M by the First Vice President, Lieutenant Colonel ALFRED A WOODHULL of the Medical Department of the United States Army, who most efficiently assisted President Liceaga throughout the entire meeting of the Association The session was opened with an address by His Honor EDGAR B JEWETT, Mayor of the city of Buffalo, who very gracefully welcomed the Association to Buffalo, and invited the members to inspect the administration of the city's affairs in their bearing upon the public health Mayor Jewett was followed by the Reverend Dr THOMAS R SLICER He said in part "I address you to night simply as a citizen of the city of the lowest death rate in the United States, who is interested in conserving the public health of that city to a still greater extent The word city is the watchword at once of your opportunity and your peril You all have seen the dwellers in the country violating all of the rules of health and seemingly being themselves healthier than those who live in cities In the grouping of so many together there is a sense of power that is not found in the country It is because of this sense of power that lies in the binding of lives together that we at once should have a sense of insecurity and a hope of power But, more than this, there is that civic consciousness which belongs to every city Buffalo, as an example, has no civic consciousness It has not the civic consciousness which marks Birmingham, Glasgow or even Chicago It is, so far as we have gone, a group of contiguous tribes I do not now refer to their nationality, though that is also true, but to their diverse interests to their alien training, to their want of common purposes in this city Chicago would not be where it is to day were it not for its civic consciousness, and if it had not had the opportunity of the Columbian Exposition Until civic consciousness arrives in municipal life it is almost a continuous upgrade for the guardians of the public health There is a constant warfare with ignorance and avarice Some of us do not know enough to protect ourselves against contagion Let me add in conclusion that the Health Department of any city has no business at that trough from which the politician feeds How many of you have not come in contact with that parsimony that will deny $1,000 for a bacteriologist and spends $2,000 on a junketing trip for a Board of Aldermen?"

The program had provided for an address on the part of the members from the Dominion of Canada, by the Honorable RICHARD HARCOURT, Provincial Treasurer of Ontario and Minister of Health but having been unavoidably detained, Dr PETER H BRYCE of Toronto, Secretary of the Provincial Board of Health of Ontario, acceptably supplied his place in a brief extemporaneous address

This was followed by the annual address of the President of the American Public Health Association, Dr EDUARDO LICEAGA, of the City of Mexico, President of the Superior Board of Health of the Republic of Mexico The President's address from the standpoint of a sanitarian in a body of advanced and experienced sanitarians was an able and forceful paper It was written in English by the President, but was read at his request by his friend Medical Director ALBERT L GIHON, U S Navy a former president of the Association It related principally to the business of the Association and went into a history of the growth and development of the study of public hygiene in Mexico, which Dr Licéaga said had been fostered and encouraged under the administration of President Diaz during the last twenty years Some of the suggestions made by Dr Licéaga were of great value and interest He laid before the Association the proposition that it should devote special attention to the study of contagious diseases, with view not only to their cure and the prevention of epidemics, but to the means of preventing the development of individual cases The several phases of the subject of epidemics were taken up separately and treated in an exhaustive manner One proposition put forth by Dr Licéaga was that isolation in infectious diseases is not so essential in some diseases as in others, and that the study of the extent to which it should be practiced would repay investigation Another proposition was that more attention should be paid to the study of the technique of disinfection These and many other phases of the broad subject of contagion could be studied by uniform methods over a vast extent of territory by the members of the Association, with great results Another question which Dr Licéaga thinks merits investigation is the ascertainment of the period within which any disease is contagious and the person affected dangerous to his neighbors This is something in regard to which much uncertainty still exists, and definite knowledge in this regard would be of incalculable value Dr Licéaga recommends also that a special committee for the investigation of the subject of the prevention of disease, particularly by vaccination and inoculation, should be appointed, and made reference to the newly developed sero therapy, which he declared was already falling into disrepute through the use of imperfect or contaminated serum A committee to devise a means for the use and sale of only absolutely pure and perfect serum, should be appointed In conclusion Dr Licéaga said "Gentlemen of the American Public Health Association, I beg to offer you my sincere congratulations on our coming again together in the twenty fourth meeting of this Association, and on having selected for the place of our meeting this beautiful and interesting city, which is so splendidly placed at the Eastern end of this delicious lake, a lake that supplies the water for this powerful river that farther on precipitates itself into a grand cataract, a stupendous marvel of nature that thousands of pilgrims from all parts of the world come to contemplate and admire, in this city which offers to us its hospitality and affords us an opportunity of again meeting to render our homage to science and to work together for the physical well being of our fellow creatures "

(*To be continued*)

Mississippi Valley Medical Association

Twenty-second Annual Meeting, held at St Paul, Minn , Sept 15 18, 1896

The meeting opened with a very satisfactory attendance, Dr H O Walker, of Detroit, presiding

Dr Charles A Wheaton, of St Paul, Chairman of the Committee of Arrangements, called the meeting to order, and introduced Archbishop Ireland, who delivered the invocation

Governor Clough of Minnesota delivered the address of welcome on behalf of the State He said he was obliged to admit that he was no orator, and that he had always been more or less timid in the presence of a physician, but of his hearty welcome to the State all members of the Mississippi Valley Medical Association might be assured

Hon F B Doran, Mayor of St Paul, delivered an eloquent address of welcome on behalf of the city He referred to the reputation of St Paul for hospitality won by the recent encampment of the G A R , and he said that upon that occasion the city had welcomed the men who had preserved the nation, while now she welcomed the men who preserved the bodies of the nation's defenders

Dr A J Stone delivered the address of welcome on the part of the profession He paid a glowing tribute to the profession of St Paul, the absence of professional jealousy, disagreement and ill feeling, while he begged to assure the visiting profession that they were most heartily welcome He also took occasion to speak of the great help the ladies of St Paul had been to the committee in making the arrangements In speaking of Minnesota as a health resort he said it had proved a Mecca for consumptives, and notwithstanding the fact that many cases of tuberculosis came to St Paul when in the last stage and when beyond all hope, die there, are included in the mortality, and notwithstanding this fact the mortality of this city is the lowest of any in the world

Dr H O Walker took the chair and thanked the speakers for the welcome they had extended In casting about for a subject upon which to deliver the annual address he had decided to relate some experiences he had had rather than thresh over the various subjects which are dealt with at length in the various medical journals He took for his title "Some Experience of Surgery of the Kidney " (To be published in full in the Journal)

The report of the Treasurer was not read, by reason of Dr H N Moyer's absence on account of sickness

The program opened in the afternoon session with a paper by Dr Truman W Brophy, of Chicago, who presented a

NEW OPERATION FOR CLEFT PALATE

He took the ground that the operation should be performed much earlier than had been done heretofore by surgeons, and that the idea that the operation should be postponed until the child reached the age of three to seven years was an erroneous one for the reason that the changes in the voice would by that time have become permanent and the correction becomes almost an impossibility The operation suggested by the author was the cutting of the edges of the cleft and then suturing them by wire sutures secured through a lead plate on each side of the palate, and made to conform to the same In the hands of the author the operation had been uniformly successful

Dr W H Daly, Pittsburg in discussion said I think the essayist has made a marked advance in the operation for cleft palate, the most important point being its adaptability to very young children, as I think it does away with all former objections to operating on the young infant The greatest disappointment I have had in these cases is the poor articulation which follows the operation, and which is always a source of great disappointment to the patient and family, who always expect to hear perfect speech immediately after an operation, and I think this result will be attained in Dr Brophy's operation

Dr G Futterer, of Chicago, read a paper entitled

PLEURITIC EFFUSIONS AND THEIR TREATMENT

The author took the ground that a bacteriologic examination should be made in all cases The diathesis in cases of pleurisy should also be most carefully looked into, as cases of uric acid are frequently found in connection with pleurisy, these yield readily to the administration of salicylates, and but about 15 per cent of the cases of pleurisy are believed to be pneumatic The pleurisy of typhoid fever was also considered by the author, who did not believe it was a mixed infection, but that it was a distinct condition As to the presence of tubercle bacilli in pleuritic effusions, Dr Futterer believed that they may enter through the alveolar septa and enter the pleura without producing serious effect in the lungs The author has washed out the cavity in fourteen cases with an antiseptic solution, with success in twelve The agar culture should be used to differentiate between tuberculosis and pleurisy The advantages to be gained by this treatment is that many patients will submit to it when they will not submit to the excision of a rib

Dr Gustavus M Blech of Detroit, read a paper on the

TREATMENT OF INFLAMMATORY DISEASE OF THE STOMACH.

The author criticised the old routine methods of treating acute inflammatory disease of the stomach with menthol, ice, cocain, opium, purgations, cathartics, pepsin, etc , for the reason that they did not cure the patient and the physician was too liable to delude himself into the belief that he had cured his patient because he did not return, which the author claimed was in nearly every instance due to the fact that the treatment did him no good The reason that was given for the failure to cure the catarrhal condition of the stomach was that we are too prone to attempt to prescribe remedies for the relief of symptoms only and not sufficient attention being given to relieving the pathologic condition which prevent the digestive process from being normal The use of strong antiseptics, which seem to be indicated are more likely to do more harm than good by reason of the destructive action of strong antiseptics have on animal and vegetable cells The treatment may be summarized into

1, destroy the morbid element which is present in the stomach so as to thoroughly cleanse the mucous membrane, 2, heal the diseased surface after it has been made aseptic For the cleansing the author has found hydrozone the most satisfactory He uses a tumblerful of lukewarm water containing a 2 per cent of hydrozone, half an hour before meals The nascent oxygen which is set free in the stomach by the oxidizing agent destroys the morbid element and cleanses the mucous membrane As a healing agent glycozone in one to two dram doses immediately after meals, is recommended This treatment is strongly urged in gastric ulcer

Dr F Hunt Stucky, Louisville, Ky —I desire to emphasize the value of perfect lavage in cases of gastritis I would also urge the careful attention to dietetics as well as any intestinal disorder that may exist in connection with the gastritis There must also be something in addition to the antisepsis, the nervous system should be built up and attention paid to any circulatory disturbance I believe massage would be valuable in many of these cases

Dr I N Love, St Louis—I do not believe in limiting the treatment to any one agent, the entire tract must always be kept in mind and the application or administration is but one of many things to be done We can not separate one set of secretory glands from another but must give attention to them all and in these cases I believe especial attention should be paid to diaphoresis, massage is also to be recommended in a certain proportion of cases I believe there are many persons suffering to day from an auto toxemia due to a disordered stomach and that 90 per cent of these cases can be laid at the door of constipation Lavage of plain water as well as drinking large quantities of water just before eating I think a great help toward starting the current downward and outward The habits of lavage has done much harm and I do not believe it should be intrusted to the patient to carry out

Dr W H Daly, Pittsburg—I have had anything but satisfactory results from lavage, the treatment suggested, and do not favor it I heartily agree with the speaker regarding the toxemia for I heartily believe that a very large proportion of these stomachic diseases are due to toxemia and the most important thing to do is to consider every one of these cases as a rule unto itself and treat them individually A good idea is to give a lavage of a gallon of water and then empty the stomach by irritating the throat with the finger when a cleansing result is desired

Dr C H Hughes, St Louis—The most important factor in the handling of this class of cases is to treat your patient all over Medical men of the present day in treating dyspepsia have been forced to the conclusion that the individual is possessed of a pneumo gastric nerve and that it plays a most important part in this disease, which has so long been considered as a local one You take for example a case of nasal catarrh which goes the round of treatment at the hands of the rhinologists, who apply the spray, cautery, remove spurs from the septum, etc , and what is the result? Are the cases cured? No, because the attendant is too prone to treat the disease as a purely local one and not through the nervous system as should be done

Dr F F Lawrence, Columbus—The frequent occurrence of dyspepsia in connection with gallstones has suggested the possibility of its being secondary to this condition We have all known of cases when the patient has consulted the physician for the relief of the usual train of symptoms which would indicate gastro intestinal disorders and without relief until an abdominal surgeon looking for ovaries he may remove, opens the abdomen and finds gallstones, after the removal of which the gastro intestinal symptoms disappear

Dr J M Mathews Louisville—I would like to suggest that the author of the paper did not attempt to treat nasal catarrh hysteria, or some of the other diseases the gentlemen have referred to The paper dealt with a certain class of gastric disease and the treatment is precisely what you would adopt should you have an ulcer or acute inflammation located in any other region and I think we should bear in mind that if we want to have successful results we must get at the local conditions in these cases

Dr H T Patrick, Chicago—I think there is some value in the suggestion of the esssayist but I am opposed to the presentation of a cure for a condition as complex in its nature as gastritis without stating more specifically what form it is I think the important thing to do first is to decide upon what particular form of the disease we have to deal with, then the cause and we can then apply our cleansing and antiseptic treatment

Dr I A Abt, St Louis—We should not for a moment lose sight of the fact that we have a pathology for all these forms of gastritis, whether it be from alcohol, tobacco or any other cause In making this differential diagnosis lavage will be of particular value I am firmly of the belief that many of these cases are due to toxins

Dr J A Larrabee, Louisville—I am convinced that the portal circulation is more often at fault in these cases than is generally supposed and its correction too often neglected Exercise is above all things the most important and should be insisted upon in order to direct the blood to other and healthier channels While I do not propose to discard the use of antiseptics I will place more reliance on treating the portal circulation

Dr W S Caldwell, Freeport, Ohio—I use the stomach tube for diagnosis purposes principally and when I find that there is neither fluid or debris forming in the stomach I keep the tube out, although where I find much fluid accumulated in the stomach in the morning I wash it out with the tube

Dr Paul Paquin, of St Louis, read a paper entitled

THE TREATMENT OF EXPERIMENTAL TUBERCULOSIS IN ANIMALS BY THE USE OF BLOOD SERUM

(It will be published in full in the Journal)

Dr H Longstreet Taylor, St Paul—I desire to say just one word on tuberclin and its modifications Although the essayist says that it acts by producing an antitoxin, yet this has not and can not be proved It may be the true explanation although the observed fact of an active leucocytosis in tubercular areas during its use is a more plausible explanation Tuberculosis in its various manifestations presents such a complicated future and such a complex one that the very existence of an antitoxin is problematic and even if found it could not be a specific in the sense that the antitoxins of the acute diseases, as diphtheria, are specifics Tuberculin is very much in disrepute here and everywhere, but it has a few constant friends yet among whom I stand, and with good reason, for in careful hands undoubted results are obtained with it I have, for instance, only recently seen the glands, in three cases of undoubted glandular tuberculosis, disappear under its use, what more convincing experiment could one desire?

In a long series of cases my results with tuberculin have been eminently satisfactory With the St Louis serum, however, I have not been able to obtain results All the cases upon which I have used it grew worse Still from a short series no results can properly be claimed, for more than in any other disease probably are statistics difficult of comparison in tuberculosis

Dr Jos Muir, New York—My experience has been large and varied in the therapeusis of tuberculous disease and for years I have used tuberculin and all its modifications, especially those of Hunter, Maclean, Klebs, Kitasato, aside from these, modifications of my own consisting of different percentages of toxic albumoses, the logic being that the maximum of irritation was gradually reached within and around that impenetrable wall, which surrounds all anatomic tubercles Dr Paquin is scarcely satisfactory in his theories regarding the physiologic action of his serum in tuberculous areas but his paper is teeming with statistics, some one has said, Beaconsfield I believe, that statistics consist of three classes, lies, damn lies and statistics The curability of consumption can not be judged by statistics Its curability has been known from time immemorial since the days of the early Greeks Milk was the great agent in the treatment and continues to be so to the present time—so from the fullness of statistics I may cite the case of Professor Emmerick in an article written by him somewhat over a year ago and in which he gave the history of ten cases of sarcoma and carcinoma cured by serum obtained of the erysipelas and prodigiosus toxins It was afterward proven that one of the cases referred to had been dead two months prior to the reading of the report

Dr Barclay, Pittsburg, Pa , complimented Dr Paquin and congratulated the profession on the earnest and honest investigations made He felt that the absolute candor of the reports should command the attention of the profession

Dr H W Loeb, St Louis, Mo—I have known several cases of laryngeal tuberculosis treated with serum and knew of one case in which Paquin's serum had given remarkably good results In others it had been less successful I consider serotherapy more promising in the treatment of other forms of tuberculosis than that of the throat I will report a case of a man who, six years ago was examined by six competent physicians who pronounced the case one of tuberculosis with a fatal prognosis The serum was used and to day the man feels perfectly well and all physical signs of the disease have disappeared except a slight thickening of the arytenoids I have confidence in the treatments in laryngeal tuberculosis, and one fact I have noted is that when first administered the larynx improves wonderfully even though it again resume its downward course

Dr W H Daly, Pittsburg—There is one thing to be remembered in our enthusiasm over any new remedy for tuberculosis and that is a very frequent occurrence to have patients claim that they are much better whenever a new line of treatment is adopted It was so with Koch, Bergeon and Edson I have tried the latter for a period of three months only to abandon it and while using it among some 150 cases of complications I had developed four marked cases of acute insanity I regret that I am forced to admit that I feel that medical science has done very little toward checking the downward career or in the diagnosis of this disease

Dr Y J Green St Paul—The full ability of medicine is best demonstrated in the treatment of tuberculosis The statistics of some of the newer remedies are very encouraging at first, but they are somewhat altered when we stop to consider how many cases of enlarged glands and tubercular laryngitis get well without any treatment. I am still inclined to t belief that we must depend more upon climate and high altitude than any thing else

Dr Joseph Muir, New York—The treatment of tuberculosis is a very vague thing We should be somewhat guarded in pronouncing a cure for the reason that many cases for a time manifest a quiescent stage which simulates cure As for the beneficial results of climate, I think more is due to the change of surroundings than to the climate

Dr Chas H Hughes, St Louis, said that one should not depend on any one remedy in the treatment of consumption

Dr Love said he knew of the work and results of Dr Paquin in his laboratory, and knew that his results in the treatment of tuberculosis were as stated

Dr Paquin, in his closing remarks, stated that serotherapy was founded on natural law It was nature's own remedy he tried to produce when he prepared tubercle antitoxin He believed that serotherapy in tubercle had passed the experimental stage, although by no means perfect He said that in the earlier stages pulmonary tuberculosis could be arrested in at least 80 per cent of the cases by the use of serum and proper adjunct treatments

Second Day

Dr Horace H Grant, of Louisville, Ky , delivered the address on surgery

THE RELATIONSHIP OF DIAGNOSIS TO THE FUTURE SURGICAL PROGRESS

He said that we must find some common ground for the settlement of our differences, many of the recent operations are passing away, owing to the effect of our modern scrutinizing investigation We forget there are men in the quiet of their laboratories doing a work which makes all our wonderful progress possible We can not progress much further in technique of operative skill Any great amount of paraphernalia suggests a lack of personal resource in the operator Almost every part and organ of the human body has been removed recently with more or less good to the patient If we would make earlier and more careful diagnosis many of the possible failures would be precluded No surgeon dare say to the patient, "If I had known yesterday, or before, so and so, the result would have been different" Rarely will we fail to secure an operation if the operator be sure of his diagnosis and demands an operation No term in all surgery is so often misapplied as conservatism No aim is dearer to the surgeon than the ways and means of relieving his patient We must not fall into the error of making one man great and another man insignificant Experience is and should be one of the greatest aids in diagnosis The skiagraph has lately come into importance in surgical work, and may be made a valuable adjunct in many instances Its recent successes are noteworthy It is yet, however, in its infancy, and is doubtless capable of still more development No one doorway can open to success in surgery The skillful and intelligent application of prompt relief added to a careful diagnosis will give us the most wonderful and satisfactory results What each one finds to do let him do it with his might

Dr E M Houghton demonstrated the action of the antitoxin on guinea pigs before the Association He called attention to the conservative view the profession had taken of the antitoxins which would have a tendency to avoid the unfortunate experience the profession had had with tuberculin The value of laboratory experiments in connection with clinic observation was emphasized by reason of our being thus enabled to obtain the exact dynamics of the flesh and blood of our patients and the advantage to be gained in varying our experiments at will In the case of diphtheria antitoxin the physiologic effect can be foretold with almost the same certainty that we can predict the formation of hydrogen when platinized zinc and hydrochloric acid are brought together The world's verdict in reference to the clinic value of the diphtheria antitoxin is expressed in the report of 615 physicians reporting to the American Pediatric Society on the use of the serum, of whom 600 are in favor of its use A similar commission appointed by the German government, came to a like conclusion, while Behring claims that after a careful estimate he thinks that 20,000 lives were saved in Germany alone by the use of the heil serum In England the results are expressed in the report of the *Lancet* Special Commission, which report That the influence exerted by the exhibition of antitoxin on diphtheria is at any rate quite as marked as that exerted by quinin in malaria Our ignorance of the true action and power of the toxins and antitoxins was emphasized The author claimed that the results obtained by Pfeiffer and his co-workers, in which he showed that if the serum obtained from the blood of an immune animal be injected into an animal infected with virulent cholera cultures the animal survives while the control animals die This result is not due to the antitoxic action of the serum but to the bactericidal substances developed when the serum is brought in contact with the living cells of the animal body If an animal be treated with large and increasing quantities of living cultures of the bacillus pyocyaneus for several months, the resulting serum will possess strong bactericidal properties but weak antitoxic properties If on the other hand the toxin is used, the resulting antitoxin will have a strong germicidal and antitoxic action This may explain why we get a more potent diphtheria antitoxin when the horse has been immunized with a diphtheria toxin than when he has been immunized

Eight guinea pigs were inoculated before the Association with diphtheritic toxin, five were then inoculated with the antitoxin and the second day saw the five in excellent condition while the other three died

The Committee on Nominations, consisting of Dr J M Mathews, Louisville, Dr I N Love, St Louis, X C Scott, Cleveland, W N Wishard, Indianapolis, J M Coulter, Chicago, W F Barclay, Pittsburg, W J Mayo, Rochester, Minn , J P Collins, Hot Springs, G Blech, Detroit, T H Manley, New York, and E W Lee, Omaha, reconsidered the nomination of secretary, and selected Dr H W Loeb

Dr Robert H Babcock, Chicago, read a paper on

A REPORT ILLUSTRATING THE VALUE OF SECONDARY PHYSICAL SIGNS IN THE DIAGNOSIS OF CARDIAC DISEASE

The author claimed that the murmurs are the least reliable signs of valvular disease and an accurate diagnosis can not be made unless the secondary signs are recognized If the heart be too weak it may be that the murmur can not be detected, or a grave defect may not be noted Secondary symptoms are a modified pulse rate, character and rhythm, leading to a congestion of the veins and internal organs In some instances there is systolic venous pulsations of the liver This is diagnostic of insufficiency even if the murmur is not audible

Dr Joseph Muir, of New York, read a paper on

REINFECTION IN CONSUMPTION

(It will be published in the Journal)

Dr J A Larrabee, Louisville—The paper of Dr Muir is unusually attractive, and reflects to us our individual experience with consumption The doctrine of re infection affords the only reasonable explanation of the recurrence of arrested tuberculosis, with which every general practitioner must be familiar The principle element in our failure to secure to the patient the advantage gained by our treatment in cases of pulmonary consumption consists in our inability to remove the patient from the surroundings in which his disease commenced The air of workshops, the carpets and drapery of the apartments, together with the illy ventilated tenements of even the well to do working people, contain abundant seed for the now more congenial soil I have always believed that if the consumptive could have in the inception of his disease the comforts and care which are drawn around him in the late stages recoveries would be far more frequent In regard to climate, I do not think that altitude or latitude are of so much importance as a sterile atmosphere to the bacilli tuberculosis Some of the saddest sights which I have witnessed in my travels both at home and abroad have been doctors' mistakes coming home in pine boxes I believe that the best place for a consumptive in the second stage of his disease, when the lung tissue is beginning to break down, is at home, no matter what or where that home may be It is a sad sight to see the suffering putting up with inconveniences and deprivations, which home alone can remove, for the questionable advantage of climate To this must be added the mental depression consequent upon absent friends and the tender touch of a loving hand Yesterday I had something to say upon lavage when the subject of gastritis was under discussion To day I simply want to change the "l" into a "g" and speak of gavage, by which I mean a systematic course of forced feeding with most nutritious food, or in a word, forced nutrition It has been sufficiently demonstrated that nutrition may be successfully forced even where there is no inclination to eat Every farmer who has stuffed turkeys in a dark cellar for thanksgiving market knows this If you can make your consumptive patient gain steadily in weight he will as certainly improve in all other respects I have sent very many consumptives to New Mexico with invariably good results, but I believe that if the United States government, as proposed, were to build a sanitarium at Las Animas or Santa Fe and fill it with consumptives, it would soon become a Lazar house of disease, notwithstanding the altitude and latitude Among many of my cases sent to this place was a young man who was fast succumbing to consumption He was a blythe and accomplished fellow, and the sole support of a widowed mother He had night sweats and copious expectoration and plenty of bacilli I sent him to Las Animas to "fence ride," herding on a ranch, he rapidly improved His clerical abilities attracted the attention of his employer, who had built a hotel, and he assumed the duties of clerk In three weeks his symptoms returned, he wrote me and I told him to get out and go "fence riding", he is still well, but would have died had he remained indoors No point is better established than that consumption is a disease of aggregation of individuals It was unknown to the nomadic tribes, and no point is more important than segregation of tuberculous subjects If I have spoken at greater length than the limit my apology is that such a paper as Dr Muir has presented should not go unnoticed, and without the compliment which it deserves

Dr HUGH T PATRICK of Chicago, read a paper with elaborate illustrations on

TRUNK ANESTHESIA IN LOCOMOTOR ATAXIA

In nearly all cases of tabes dorsalis there is a band of anesthesia about the trunk of about the level of the nipple It is early in the disease very narrow or even incomplete, or may be represented by a zone in which the localization of touch is not normally accurate The sensory blunting on the legs so frequent in tabes is generally an analgesia, the trunk anesthesia is ascending, tactile, and the pain sense may be quite normal The band of anesthesia does not correspond to the cutaneous distribution of the intercostal nerves, but to the nerve fibers arising from adjoining segments of the spinal cord In some cases there are two distinct zones of anesthesia indicating simultaneous involvement of spinal segments at some distance from each other The borders are inconstant, ordinarily retract on continued testing, and vary in position with the method of examination The same band of anesthesia may occur in syphilitic pseudo tabes as shown by an illustrative case, as far as known the only one on record The patient presented nearly all the principal symptoms of locomotor ataxia, including a wide band of trunk anesthesia, but a diagnosis of syphilis of the cord was made, and on active specific treatment he made an almost perfect recovery A zone of anesthesia much narrower than this one still exists

Dr J FRANK of Chicago, presented a paper on "A New Method of Fastening the Round Ligament in Alexander's Operation"

Dr J A ABT of Chicago, read on "The Clinic Significance of the Child's Fontanelle"

Dr W J Mayo of Rochester, Minn, read on "The Surgical Treatment of Pyloric Obstructions"

Dr THOS H MANLEY of New York read a paper on

CONDITIONS WHICH MAY SIMULATE ORGANIC OBSTRUCTION OF THE RECTUM

The obstructions in the large intestine are of two kinds, viz 1, the passive, 2, the chronic or incomplete The former are the most rare and dangerous, with few exceptions depending on hernia, paresis, or occlusion by a new growth The latter derange the general health though they seldom immediately imperil life They are essentially dependent on habit, occupation or senile changes, or occur secondarily in consequence of extrinsic influences They are more common in the female sex in consequence of difference in the anatomy and functions of neighboring organs, and may give rise to such symptoms as may lead the unwary into suspecting uterine disorders

By a methodic systematic examination of cases of intestinal obstruction we may generally be enabled to determine whether the large or small intestine is the seat of stenosis or occlusion by certain well defined symptoms and when the large intestine is the seat of the trouble, we may determine not only the area involved but likewise whether such obstruction proceeds from causes of an intrinsic origin or from pressure conveyed through the other sources

Dr I N LOVE, St Louis—The paper of the essayist is a most practical one on obstruction in the rectum which is a most serious condition It is serious if present in the male and doubly serious if present in a woman There can be no question on the part of those who have been engaged in the practice of medicine for any length of time that 90 per cent of the diseases of women are dependent on constipation These patients suffer not only from general poisoning from accumulated ptomains and auto infection, as it were, but in addition there are encroachments and misplacements of the bowels, on the pelvic organs depending upon the regular accumulation of the fecal matter which produces mechanical obstruction The average woman, be she mother or daughter, has not been sufficiently impressed of the danger of constipation We all know that the old saying the standard of comparison as it were, regarding constipation which was explained in the words 'as constipated as a school marm or an owl," was correct We have all met with women young and old, moving in respectable society, whose bowels have not moved for ten days, two or even three weeks, yet these people are surprised if dangerous diseases overcome them Fatal inflammation of the peritoneum and many other similar diseases in women are superinduced by constipation We should impress women young and old that it is not only unesthetic and unartistic, but not healthful for their bowels not to move every day Let us impress them of the fact that to overcome this condition cathartics and purgatives are objectionable, they will have removed the immediate disturbances but they produce weakness and are agents in the establishment of the constipation habit Proper diet and eating of large quantities of fruit, together with an abundance of pure water, and especially exercise, will in nearly every case relieve the trouble Let me emphasize the importance of the use of a great volume of water morning, noon and night, let us teach our patients not to drink water because they are thirsty, but for the purpose of washing out their alimentary system of sewerage The fact that the essayist has cited a case where he with difficulty removed a fecal mass with the obstetric forceps from the rectum must be accepted by us We have all had experience along that line calling for the scooping out of accumulated masses menacing the health of the individual Women are very lax of exercise, an every day necessity let us teach them that a proper open condition of the rectal canal is necessary to cleanliness, to the system, and cleanliness is next to godliness

Dr N H PIERCE of Chicago, presented a new "Submucous Linear Cauterization, a New Method for the Reduction of Hypertrophies of the Conchæ"

Dr HUGH T PATRICK of Chicago, read a paper on

ELECTRO THERAPEUTICS AND ELECTRO DIAGNOSIS SIMPLIFIED

Electro diagnosis is limited to the affirmation or denial of a lesion of the lowest neuron, that is, of a lesion of the motor cells in the spinal cord or of the nerve fibers, the peripheral nerves springing from these cells A lesion of this neuron causes reaction of degeneration and this stripped of all unnecessary technicalities may be recognized by two variations from the normal, namely A loss or very considerable diminution of the faradic contraction and the slow worm like contraction of the muscles to interruptions of the galvanic current In the electro therapeutics of organic disease of the nervous system applications of electricity to the brain may be entirely discarded as useless Electricity through the spinal cord is little better In diseases of the peripheral nerve it probably hastens recovery and that current is to be chosen which the better causes muscular contractions In functional nervous disease electricity is of more practical value than in organic affections, but it is almost impossible to determine what proportion of this good effect is due to mental impression and suggestion The galvanic current is to be chosen for facial and intercostal neuralgia, and sciatica, the faradic for lumbago, for hysteric and anesthesic paralysis and pain The galvanic for exophthalmic goitre and sometimes for neurasthenic headache and backache For facial spasm, tic douloureux, spasmodic torticollis tremor and chorea electricity is useless aside from the mental effect

Dr J A LARRABEE, Louisville—I arise, Mr President, to tender my personal thanks to Dr Patrick for his plain, succinct and truthful elucidation of the application to bodies of which we know little, of a subtle fluid of which we know less I thank him because he has made the subject of electro diagnosis and therapeutics plain to my mind, which is a difficult task Hitherto papers presented upon this subject have been chiefly interesting to their authors Dr Patrick has plainly shown us what lines are to be expected from electricity It is not surprising that electro therapeutics should afford a fruitful field for quackery and then it should be surrounded with all the mysteries of his ingenuity I will say in conclusion that I have not found any benefit from electricity in chorea, nor should I expect that any benefit should accrue if the accepted pathology of that disease obtains

Dr A J OCHSNER of Chicago, in a paper on

NERVE SUTURES AND OTHER OPERATIONS FOR INJURIES TO THE NERVES OF THE UPPER EXTREMITY

It presented the following conclusions

1 Suture every severed nerve 2 The earlier the operation the better 3 If neither sensation or motion is established within a year the nerve should be again exposed the cicatricial tissue removed and the ends again sutured 4 The ends should be clean cut, should contain neither crushed tissue nor cicatricial tissue 5 Tension must be avoided 6 The wound must heal without suppuration to secure the best results 7 Hemorrhage should be controlled perfectly to prevent intervening clot 8 Carefully prepared catgut is the best suture material 9 After suturing the ends either direct or 'a distance' it is

well to stitch a fold of fascia over the united nerve ends 10 The extremity should be placed at rest 11 The external incision should be ample

Dr H P Newman of Chicago read a paper on

WOMAN AND HER DISEASES VERSUS GYNECOLOGY

The author emphasized the following points 1 As specialists we must recognize and exercise the rising interest in a medical science which shall be preventive rather than curative 2 Our affiliation should be with the general practitioner and obstetrician rather than with the specialist in surgery, who often lacks the special training necessary to an appreciation of the many disease manifestations in woman, their etiology and prophylaxis 3 As we have long made a study of the pathology and etiology of woman's diseases and as we know that whatever may be acquired can be prevented, our specialists are best qualified to lead in the movement for the reform of all conditions detrimental to the health of modern women

Dr J H Coulter of Chicago read a paper on

TONSILLOTOMY BY CAUTERY

He gave the following conclusions 1 Do only a small amount at each heating of the electrode—work five seconds and allow the patient to rest twenty seconds 2 Burn only where you can see what you are doing 3 Use an electrode bent at right angles and having a fine point 4 Do not attempt too much at one sitting 5 A strong solution of silver nitrate is an excellent hemostatic in cases where there is slight hemorrhage 6 Be sure the electrode is thoroughly heated when you attempt to burn 7 Cut off the portion loosened at each séance, it prevents healing by its friction, and is often an annoyance to the patient 8 Do not operate if the gland be acutely inflamed 9 Always remember the normal shape of the tonsil, and that one must dissect much more deeply at its superior portion in order to get all of the pathologic tissue 10 It is sometimes best to cut from below upward while taking out the inferior portion, in this convenience should be the guide 11 By care the operation may be rendered almost if not entirely bloodless 12 The indication in all cases is *eventual* total ablation 13 Succeeding steps on the same tonsil should not be more than ten days apart 14 When hemorrhage is met with, stop the bleeding at once with the heated electrode, and apply a solution of silver nitrate 90 grains to the ounce solution or stronger 15 Try the method in suitable cases and I feel confident you will concur with me in the opinion that it possesses some advantages not found in any other

Dr G Blech of Detroit read a paper on "Kola"

Dr F F Lawrence of Columbus, Ohio, read a paper on

THE PATHOLOGY AND TREATMENT OF SUPPURATIVE SALPINGITIS

He called particular attention to the following points 1 The tubal mucosa is a true mucous membrane possessed of all the histologic elements of mucous membrane 2 The fimbriæ are prolongations of the folds of mucous membrane with a few muscular fibers beyond the end of the tube proper 3 The closure of the fimbriated extremity of the tube is effected by first, the unfolding of these plicæ and the elongation of the muscular fibers with coincident inflammatory exudate and not by adhesion of peritoneal surfaces 4 The closure of the tubal ostium results in the formation of a circumscribed abscess 5 The pathology of this circumscribed abscess is the same as that of suppuration with abscess formation in mucous membranes in other parts of the body except in the effect upon important contiguous tissues 6 Occasionally the uterine end of the tube remains patent when we have the abscess of tube communicating with uterine cavity through which it may impart, discharge its contents The treatment of the tube can not be fixed by any ironclad rule, each case must be treated as best it can by first, incision and drainage in rare cases second, the vaginal section in a few carefully selected cases, third, abdominal section in a great majority of cases, hysterectomy in those cases where we find abscess of uterine wall, tubercular deposits, fibroids or malignant disease of fundus, as hysterectomy destroys the pelvic floor, it should never be performed except when there is some tangible lesion of the uterus

Dr F B Turck, Chicago—I wish to take objection to the manner in which the speaker handled the bacteriology and pathology, in his paper, of the uterus and tubes In the first place microorganisms do not peptonize living cells It is only necrosed tissues that undergo peptonization The manner in which infection takes place is, first a *soil is found upon* the surface of the mucosa—the microorganisms may develop in a mucous bed of cellular lining upon the mucous wall As the germs grow in this rich nutrient media toxins are found which are partly taken up by the underlying gland cells A necrosis then occurs and the cells exfoliate and add to the nutrient media It is then that peptonization of the necrosed cells may occur The thinning of a tube is not due to the peptonization of its wall When inflammation of the mucous membrane of the tube occurs, the membrane first may be thickened, then fluids are formed which distend the tube or tubes, and the pressure in this manner produces a thinning of the walls

Dr H H Grant, Louisville—While I believe the position taken by the essayist is practically the one we must accept, it is not the ideal one We are often forced to accept what our judgment indicates to be a second choice There are two arguments not mentioned which, while they are in the minds of the essayist and the surgeon, are not in the minds of the general practitioner and the family, and do not assist in securing consent to operate These are First, there exists always, practically, a septic condition and often a gangrenous foreign material of a highly dangerous character Secondly, there is a large proportion of apparent recovery which are in fact but partial recovery When we can so instruct the general practitioner that he will understand the patient who lies before him has within his abdomen a virulent foreign body or pus sac, he will not hesitate to consent to and advise operation Beside this when there is impressed on the patient the danger of recurrence, even after apparent recovery, he will more likely accept the operation With respect to septic peritonitis a serious question arises Whether to operate or not is still unsettled It is humiliating to decline and often hopeless to proceed

Dr I N Love, St Louis, read a paper entitled "Water" (To be published in full in the Journal)

Dr T H Stucky, Louisville—I want to say a good word for hydrotherapy, but I would take issue with the essayist that a large quantity of water is always to be taken with meals, for example, in cases of dilated stomach I do not think it at all advisable, it also prevents thorough mastication when taken with food and thereby prevents complete salivation which would result in fermentation I also think that too little attention is paid to the subject of water in our medical colleges

Fifty seven members of the Association left in a special train for Yellowstone Park Friday evening and arrived at the Park Sunday noon They expect to return in a week

Second International Congress of Gynecology and Obstetrics

This Congress opened at Geneva September 1, with a notable gathering of specialists from every civilized country The first address was made by Bouilly of Paris, with Kelly of Baltimore and Sanger of Leipsic as "co rapporteurs," and discussion by Henrotin of Chicago, Péan, Hartmann, Richelot, Tait, Doyen, Delagenière Laroyenne, Jacobs, Delettrez, Rouffert Tournay, etc Bouilly defined as follows the indications for simple incision with drainage, through the abdominal or vaginal wall

1 An acute pelvic abscess of cellular origin, the point for the incision indicated by the projection of the collection in the abdominal wall or in the vagina 2 Primary peritoneal collections consecutive to puerperal, abortion or gonorrheal lesions, acute or subacute, or to post-operative peritoneal infection 3 Suppurated hematoceles 4 Encysted pelvic abscess in the adnexa, unilateral, with not very thick walls, easily fluctuating, and located low down on the uterus so that it can be pushed down by pressure in the hypogastric region into contact with or near, the wall of the vagina Simple incision is also especially indicated in acute suppurations of the ovaries or tubes accompanied by general serious conditions in which the extreme virulence of the pus contraindicates laparotomy or hysterectomy This method of treating pelvic suppurations gives better results and ensures recovery in far more cases than is generally realized, while if a fistula persists or the suppuration returns, it does not preclude a later vaginal hysterectomy

Laparotomy is indicated whenever there is any doubt as to the character of the lesion or whether it is uni or bi lateral The latter consideration is less important in the case of suppurations, as it rarely happens that suppuration of one side is not followed by the same condition in the other Laparotomy is also the better method for pockets located high up, when they are near the horns of the uterus and yet far enough away from it and from the vaginal cul de sac for the uterus to retain a certain independence and mobility, also when the pockets are rather abdominal than pelvic, not surrounded by thickened and indurated tissues, and when they have not produced repeated pelvi peritoneal disturbances The opening of such a pocket in the course of a vaginal hysterectomy might produce an acute peritoneal infection by infecting the surrounding intestines unprotected by any old barriers of organized adherences Aside from these two restrictions, uncertainty as to the nature of the lesion and an elevated location, vaginal hysterectomy accomplishes all that can be accomplished by laparotomy in the removal of suppurated tubes and ovaries or a small pyo salpinx It also reaches and cures lesions for which laparotomy is useless or too dangerous It is the only method which reaches purulent collections enclosed in the appendages, circumscribed by adherences or merged in the neighboring parts, and separated from the great peritoneal cavity by solid and organized tracts, actual fibrous processes which render laparotomy useless and any attempt at enucleation dangerous Hysterectomy is also the preferred method in cases of large, adherent pockets, impossible or difficult to enucleate, with or without fistulas It is also the best method to cure chronic suppurations of the peri uterine cellular tissue that have opened spontaneously and formed communications with neighboring organs In these operations the purpose is simply to evacuate, the ablation of the uterus forming an ideal means of draining through which the collections discharge and dry up To extirpate the pocket itself under these circumstances deprives the operation of all the advantages of its simplicity and benignity, and shows a misapprehension of its chief advantages In conclusion he stated that ablation of the uterus is a factor not to be neglected in the treatment of pelvic suppurations Some of the laparotomists now remove the uterus along with the adnexa as this ensures perfect drainage of such marvelous efficiency that it is probably the cause of the superior results after vaginal hysterectomy Ablation of the uterus also prevents future trouble from that organ The immediate recovery is more rapid and the after effects are better, while the genital disturbance subsequent to suppression of the menstrual function seems to be less after ablation of the uterus with the appendages, than after ablation of the latter alone Vaginal hysterectomy therefore, is the method *par excellence* for treating pelvic suppurations and laparotomy only exists on its contra indications

Sanger, on the other hand, stated that the tendency in Germany is to favor laparotomy and ligatures, and a more conservative treatment The Germans consider that it is far better to retain as much as possible of the genital organs than to extirpate them and resort later to the ingestion of ovarian tissue, etc , as a substitute for them He rejects absolutely the idea of vaginal removal of a sound uterus as a preliminary to operating upon the adnexa, and states that the radical operation is not justifiable when the abdominal end of the tube is still open, nor in light cases of purulent salpingitis abscesses of the ovaries, chronic, non purulent affections of the adnexa, nor in simple, chronic inflammations of the uterus

It is beter to have a menstruating uterus, even if it is slightly diseased, rather than none at all On the other hand, the radical operation is completely justified in serious suppurations of the adnexa, pelvic peritoneum, or connective cellular tissue, when these affections coincide with a serious affection of the uterus, which alone would justify its removal, and also when the purulent affection of the adnexa has spread to the uterus, also in cases of tuberculous affections Proximity to the menopause is an additional indication for radical treatment The objections to vaginal operations are the necessity of commencing the operation at the uterus instead of at the diseased ovaries, also the impossibilty of arresting the operation, the incompleteness of the investigation of the field of operation as other purulent collections, appendicitis, etc might exist and pass unobserved, the impossibility in certain cases of a truly radical operation, and the dangers of hemorrhages and of injury to the neighboring organs In the case of slight suppuration of the appendages, when the pockets were not opened in the course of the operation, the peritoneal cavity can be closed without danger The Germans prize highly the method of closing introduced by Kaltenbach and Olshausen, except in serious cases of radical vaginal operations When ever removal of the uterus is indicated, he considers celio salpingo oophoro subvaginal hysterectomy as the least dangerous radical operation A part of the ovaries can even be retained with it Drainage is indispensable in all cases of contamination of the hand of the operator or of an intact region with virulent pus, also when the hemostasis is not perfect or there is a discharge of virulent pus, also where there is a preexisting fistula, or perforation of the intestine during the operation He prefers Mikulicz's method of drainage, and adds that thanks to this, the life of the patient can always be guaranteed, with complete recovery in time Tamponing also relieves the anxiety of those who venture to close the abdomen He classified some of the various methods in vogue as follows

Vaginal methods 1, anterior colpo celiotomy (Duhrssen, A Martin, etc), 2, posterior colpo celiotomy (Steel, Hegar, Battey, Byford, Laroyenne, Landau, Mackenrodt, etc) 3, anterior and posterior colpo celiotomy (Bode, Von Erlach, Gottschalk), in combination with uni lateral and bi lateral salpingo oophorectomy, 4 colpo hysterectomy (Pean's uterine castration), colpo hystero salpingo oöphorectomy or radical vaginal operation (Pean, Segond, Doyen, Landau) Abdominal methods 1, celio salpingectomy and uni or bi lateral celio salpingo oophorectomy, 2, total *celio salpingo oophoro hysterectomy* (Krug, Polk, Delagenière, Schauta, Bardenheuer, etc) 3, bi lateral celio salpingo oophorectomy combined with supra vaginal hysterectomy (Zweifel, Kelly, Sanger) Mixed methods Abdomino vaginal hystero salpingo oophorectomy commencing usually with the vagina and ending with the abdomen (Landau), and finally, in a group apart, sacral or parasacral celiotomy (Hegar, Von Hochenegg, Czerny, Schede etc), which has only been performed by a few surgeons and with strict limitations

Kelly's able presentation of his methods was read by the Secretary General Henrotin (Chicago) insisted on the benefits of immediate vaginal incision with digital exploration, and if necessary a second opening in the anterior cul de sac

Richelot *(Paris) remarked that extirpation of the adnexa* through the abdomen was not always followed by recovery, and the surgeon was sometimes baffled by encountering extremely virulent pus In every second one of the laparotomies he has performed since 1894 for suppurated adnexa he has been compelled to finish with double castration Laparotomy triumphs where there are organs to be respected, which is he considers, its true indication He added that the tubes and ovaries are not heard from after the removal of the uterus as often as the uterus after the removal of the appendages concluding with the statement that vaginal hysterectomy should be accepted as the preferred method of treating pelvic suppurations, principally because it avoids the two dangers of laparotomy infection of the peritoneum and injury to the small intestine Hartmann (Paris) urged more general resort to repose in bed and vaginal antisepsis as the first and sometimes, the only treatment needed for pelvic suppurations He has also derived great benefit at times from dilatation and curettement which may prove useless, but in certain cases seem to be all that is necessary Pean lauded total vaginal castration as applicable to all pelvic suppurations of genital origin and sure to produce better results than any other method of treatment Recovery is more rapid the earlier the operation is performed, and the mortality, in skilled hands is only from 1 to 4 per cent He concluded by mentioning the beneficial results he has observed *occur in from two months to three years after the* operation disappearance of hysteria in 6 patients, of nervousness in 2, insanity 5, melancholia 1, morphinomania 2, ileo lumbar neuralgia 4, mammary and intracostal neuralgia 3, nausea and rebellious gastralgia 2, anemia from inanition 2, headaches and sweats 4, inability to walk 1, gravel and nephritic colic 1, rheumatic endocarditis 1, bronzed pigmentation 1, and albuminuria 2 Péan now has a record of 350 operations and repeats his previous announcement, that total vaginal castration requires a special set of instruments, such as he has been using since 1883

The other subjects discussed at the Congress were "Surgical Treatment of Retro deviations of the Uterus," presented by Kustner, Polk and Pozzi, and the discussion led by Martin Bouilly, Lawson Tait, Doyen, Jacobs, Edebohls (N Y) Gill Wylie, Delettrez, Stapfer and Petit, "Best Method of Closing the Abdomen," presented by Granville, Bantock and La Torre, discussion led by Martin, Tait Richelot Laroyenne Doyen, Jacobs, Edebohls, Gill Wylie, Byford (Chicago) and Delettrez and 'Relative Frequency and Shape of Abnormally Small Pelvis in Different Countries," etc , which were represented by Fancourt Barnes, Dohrn, Fochier, Kufferath, Lusk, Rein, Pawlick, Pestalozzi, Treub and Barry Hart

---

Fourth International Congress of Criminal Anthropology

This interesting assemblage of the specialists who are fostering this infant science opened at Geneva August 24 Lombroso said in the course of his address, in regard to our prisons that as at present conducted the expenses have to be borne by the law abiding citizens and they fail to reform the criminal The probation system with work in mines, penal farms, etc should take the place of our present prisons and criminals from passion and political *criminals* should not be imprisoned at all as exile alone is more than sufficient punishment. Confirmed criminals, epileptics, alcoholics should receive special medical treatment, but the *efforts of society should be espe* cially directed to bringing up in a moral atmosphere the born "criminaloids" from the earliest months of their lives, with absolutely no intercourse with depraved associates and no opportunity for them to corrupt decent young people. With this should be combined every possible means to combat alcoholism, social, religious, with journals, pamphlets, etc., and constant medical supervision of the "criminaloids." Francotte spoke of a condition induced by alcohol which he calls alcoholic somnambulism. The individual acts in an apparently normal manner, but has no consciousness of his actions, or at least retains no remembrance of them. He considers it a legally irresponsible condition, except in cases of premeditated intoxication. Legrain's address was an appeal that the importance of alcoholism as an evil and peril to the nation should be inculcated in every way, taught in the schools and impressed upon legislators as their guiding principle. Habitual drunkards should be incarcerated, so that they could not propagate their kind, and compulsory cures legally enforced. Their children should be taken from them and societies formed for this purpose. Garofalo suggested that criminals should be classified as follows: 1, assassins, 2, violent, 3, dishonest, 4, cynics. Homicidal mania, pyromania and epilepsy would be included in the first category, hysteria and kleptomania in the third and sadism in the fourth. If penal science were relieved of some of the conventionalities which now encumber it, and the actual criminals separated from the mere revolts and disobediences, each type of criminal could then receive appropriate treatment and the science be established on a firm basis. Malarewski stated that the establishment of medico-pedagogic institutions and agricultural training colonies is the only means to reclaim children with a predisposition to degenerates, and that an international medico-pedagogic congress is the only means to accomplish the organization of such colonies. Other subjects presented were the influence of the press on criminality, anarchism from the point of view of criminal anthropology, or as Zakrewski prefers to call it, legal psychopathology, digital imprints and Bertillon's discussion of the gaps still to be filled in anthropometry. The members from Russia, Italy and Belgium were especially prominent in the Congress.—*Gaz. Méd. de Liège*, September 3.

SELECTIONS

The Progress of Scientific Medicine and Pharmacy in China, A Conversation with the Physicians of Li Hung Chang.—With the great Chinese warrior and statesman who has just honored our country with a brief visit, there came two attachés of the Chinese Imperial Medical Service, Drs. Irwin and Mark, for the purpose of insuring his health and physical comfort during his journey around the world. It has been the pleasant privilege of the writer to call upon these custodians of the bodily welfare of the Viceroy, and to talk with them in regard to the recent progress of western medical methods in the Celestial Empire.

Dr. George Mark's manner is most cordial and in every way pleasing; his English is so thoroughly excellent, that only his physiognomy and dress betray his nationality. He is in the foremost rank of the Chinese students of scientific medicine.

Dr. Andrew Irwin, an examiner and director of the Imperial Hospital at Tien Tsin, is a genial Briton, who has come to favor and position among scientific men who are struggling to supplant the barbarous myths and superstitious practices of the Chinese physicians by the more human and more scientific methods of our western civilization. He appreciates the need of a change of this sort and the value of the progress already made, and finds pleasure in making known the condition of his favorite science in the country that has become the scene of his life work.

When the first medical missionary arrived in China in 1834, he found the medical methods of the country in a most deplorable condition. There was a scanty medical literature, of which one of the most important works was the Materia Medica of Li Shi Chan, which is known as the Pun Ts'o Kong Muk. Its first edition of forty volumes appeared near the close of the sixteenth century; the last of the four reprints was issued in 1826. This materia medica was a most inclusive one and it necessarily included many useful substances, as is shown by the following quotation: "Whatsoever things are produced in the world—birds, beasts, creeping things and fishes, which are generated and have blood and breath; like wise flowers and trees, which are generated, but are without blood and breath; and also inanimate objects, such as rocks and hard iron—all of these can be used as healing medicines." There had been a so-called Imperial Medical College in Pekin since the thirteenth century, but it imparted no regular courses of instruction, rarely conferred degrees, and the skill and learning of the members of its faculty were reserved for the requirements of the royal family and the members of the court.

The native practitioners were divided into three great classes: 1, the class of specialists, of which there was a subclass for nearly every division of the human body; 2, a class whose attention was given solely to diseases of the internal organs; 3, a class that treated only external diseases. A case is often cited to illustrate this condition of affairs of which it is related that a man wounded by an arrow was first visited by a physician for surface maladies. He broke off the shaft of the arrow at the surface of the body and told the patient that further treatment must be had at the hands of a physician skilled in the diseases of the internal organs.

Acupuncture and cautery by the moxa were much in vogue; counter irritation was practiced by vigorously pinching the skin with the fingers, or by harshly scraping it with a stick dipped in water or oil, and by use of various plasters. The Chinese were pioneers in the art of massage, a rude form of it forming a part of the regular operations of the native barber-shops. Surgery was almost unknown and its advance has been very greatly hindered by the belief that for well being in a future state, the body must be kept intact; hence, we hear of the pulverizing and swallowing of extracted teeth, of the eating of an excised part, or of its preservation for burial with the body after death. The medicines used were notoriously inert in many cases, and were often most disgusting in the method of their preparation or in their origin. The right to professional rank had been passed from father to son as property is inherited. In the case of a break in the line of succession, the professional privileges were sold along with the estate. Almost no study was necessary to inspire the patients with awe and faith, if the right to practice had been obtained by either purchase or inheritance from a family having a reputable ancestry of noted physicians. It has been said that "Were all of the native practitioners in the empire at once swept away, the Chinese people, so far as their prospects of health and longevity are concerned, would sustain no very serious loss."

During the last half century, the labors of the medical missionaries and other physicians from America and Europe, have done much to relieve the immediate sufferings of the people and have worked a very marked change in the practice of the native physicians in the more accessible parts of the empire. Between fifty and one hundred hospitals have been established by the efforts of various denominational organizations, and more than two hundred medical missionaries have taken part in the work, including more than a score of women. Many Chinese men and women have been trained for physicians and nurses in the hospitals, or in private study with the physicians. An association was formed in 1887, called the Medical Missionary Association of China, of which the official organ is the *China Medical Missionary Journal*, at present edited by S. R. Hodge, of Hankow, and published quarterly at Shanghai by the American Presbyterian Mission Press. Many medical works and treatises on the allied sciences have been translated into the Chinese language. Dr. John G. Kerr, an American medical missionary who went to Canton in 1854, has been especially active in this work, having issued more than twenty-five medical text books in the Chinese language. Fryer has translated the chemic treatises of Bloxam and Roscoe, and also several books on physics, botany, materia medica, etc.

The late Dr Osgood, an American medical missionary, issued a Chinese edition of Gray's "Anatomy", Hunter has translated Squire's "Companion to the British Pharmacopeia" Martin, Smith, Allen and the Chinese physician Suvoong, are to be included among the names of those who have made contributions to the literature available for Chinese medical students who read only their native language

More than one hundred American and European physicians not connected with the missions, have taken up their residence in China, and are engaged in private practice A Hong Kong Medical Society has been formed by the physicians of that city, a volume of their transactions was published in 1889 Dr Irwin mentioned Drs Manson and Canthe, since retired, as among the most prominent of the founders of this society Each of the ports open to foreign commerce has a "Surgeon to the Customs" In 1870 the Inspector General of Customs issued a request for a semi annual report from these medical officers of the different ports in regard to the condition of the health of foreigners and citizens in their respective provinces, together with the results of studies of new diseases or of diseases rarely met outside of China These reports are published annually under the title "China Imperial Maritime Customs, Medical Reports".

Dr Irwin described the founding and success of the Imperial Medical College of Tien Tsin, in connection with the Yang Ping Yuen (Imperial Hospital of the North), with great pride and feeling The first class was examined for graduation in 1883 Of the eighteen candidates for diplomas, twelve passed Dr George Mark, of the Viceroy's party, was at the head of his class, of which another member is now in America for the completion of his medical education The school was not reopened until November, 1893 There are now twenty six students enrolled, eleven in the second year class and fifteen just beginning The course of study requires four years for its completion There is no separate school of pharmacy, but the students of the medical school are given instruction in the preparation of medicines The school and hospital are both in charge of Dr Houston, an European There are four regular lecturers, one European and three Chinese The medical officers of the Navy often lecture also, when their vessels are stationed conveniently The hospital has sixty five beds and is taxed to its utmost capacity There is also a hospital for women, having thirty one beds, which is in the charge of Mrs Dr Howard King, formerly of Philadelphia

Dr Kin Ta Chin, a member of the class of 1883 of the Imperial Medical College, has been decorated for his services as commander of the field corps of the Imperial Medical Service during the recent war with Japan, and is now in charge of the field hospital of the army of North China at Kin Chou

Dr Irwin spoke in most complimentary terms of the assistance rendered by the surgeons of our navy during the Japanese war Especial mention was made of the work of Dr Philip Leech at the Isabella Fisher Hospital, which is superintended by an American woman, Dr Rachel Benn, and also, of the valuable services of Dr Ames, who has been consulted by the Viceroy, and who ably assisted at Che Foo in caring for the wounded from Port Arthur and from the naval engagement of Yaloo

"We place no reliance on the medicines of local manufacture" said the doctor in reply to a query, "but use only those imported from Europe and America Many of the large manufacturers and dealers have branches or agencies in the Empire The government contracts for drugs and medicines are a small matter in time of peace, five hundred gold dollars would cover the whole bill for one year"

There are drug stores kept by foreigners of different nationalities, and quinin and some other foreign drug staples are found on the shelves of the natives shopkeepers

A number of American and English dentists have established offices in the larger cities but very little advance has been made among the native workers Chinese dentistry is crude and a fakir's art Mercurial preparations are used for loosening the diseased tooth, when it is extracted by means of a string or rude forceps—often with a sleight of hand accompaniment to prove to the patient that the trouble in the aching tooth is due to a worm A worm is smuggled into the patient's mouth during the operation, again removed and exultingly exhibited Artificial teeth are made from bone and fastened in the mouth by attaching them to the sound teeth with a wire or a string

Now that the government has evidenced its appreciation of modern scientific medical methods by establishing and maintaining a school in which they may be taught to the youth of the land, and men from all parts of the empire have had occasion to either experience or witness their success and benefits during the recent war, we may safely regard this as the era of the triumph of science in China—we may hope that the day is not far distant when plasters of powdered tiger's teeth have lost their repute as remedies for the healing of external injuries, when jelly prepared from bear's paws has lost its alterative power, when potions made from the horn of the hart are no longer used for the renewal of wasted vitality, when Chinese mothers can eat chickens, ducks or turtles without fear of destroying the hearing or eye sight to their unborn babes, or can look upon a hare or rabbit with no qualm over a possible harelip for the unborn one —E E Ewell in *Pharmaceutical Era*, September 10

A Case of "Sadism," or Sexual Perversion with Violent Tendency —Dr Morton Prince, in *Boston Medical and Surgical Journal*, reports a case of this nature in a male aged 22 years By "Sadism" is meant the association of cruelty or violence with lust, the name being derived from the notorious Marquis de Sade, whose obscene novels treated of lust and cruelty

Dr Prince's patient before coming under his observation had been regarded as being the subject of neurasthenia or hysteria His relatives made a diagnosis of general laziness, while others described him as being not quite right His mental state was unknown to others until, after great difficulty, Dr Prince obtained a full confession It was his custom to lie upon the bed in the daytime and fall into a sort of trance or day dream state, in which he was apparently between waking and sleeping He said he thought he was awake, because if anyone should knock on the door or come into the room he would know it While in this state he used to imagine that he killed and mutilated women It was not possible to learn from him the exact mode in which this habit began, or what was the original exciting occasion, but his imagination began in a moderate way and afterward extended At first, it was only a single woman whom he imagined he thus mutilated, but afterward in each "seance" he destroyed great numbers His imagination seems to have created actual hallucinations, for he said that at these times he actually saw his victims with great vividness as objective realities and had the sensations of actually killing them, for the time being his acts were absolutely real to him, and soon a belief in them persisted

At first it was a single girl whom he mutilated, he killed her, tore her to pieces and ate her, later he imagined that he lived in towns where it was the custom for the men to destroy all the women in this way Then, as the habit grew, the towns became cities and the cities countries These countries were completely depopulated of the women by the men, all of whom together held these Sadistic feasts

While indulging in these dreams or hallucinations, he had most intense sexual excitement with emissions His habit was thus a form of masturbation, the peculiarity being the association of sexual feeling with hallucinations of cruelty When in the waking state he seemed to be at times confused as to whether he actually committed these imaginary murders or not, for while at one time he said he had not, at other times there was sufficient confusion in his mind to make him think that he had committed these unpardonable sins and to be in great misery in consequence, he would then be in a state of great penitence, which was not understood by his mother until this confession was obtained He also admitted to me that at times he thought he had actually committed these acts He had practiced this habit from the time he was 10 years old until about 20, that, is up to about two or three years ago During the last two years this habit had largely died out, but there has been (September, 1895) a tendency to recurrence It was apparent that such a person was dangerous to the community and that at any time there was a possibility, under favorable conditions, that he might put what had hitherto been pure imagination into actual practice, we therefore sent him to an asylum without delay He denied that in mutilating the bodies of his victims that he selected any particular parts of the body, as is the case with many Sadists

His general condition was one of neurasthenia He had much depression and suffered from great anguish of mind from which he broke down and cried at times, saying that he "suffered intensely," but could not describe very definitely from what particular feeling, it seemed to be more an anguish of mind

His heredity is bad, and throws light upon the distinctively degenerate character of his mental condition His mother was excessively neurasthenic One maternal aunt was described as nervous, with abnormally fixed ideas on certain social subjects, and two maternal aunts suffered from hysteria A maternal brother was delicate and always on the point of breaking down His maternal grandfather was a very able and physically strong man, with decided elements of genius He is well known to the public and recognized to be very brilliant mentally, but a man of very extreme opinions Up to the age of 40 he had a tendency to melancholia The maternal grandmother was neuralgic, ailing, neurasthenic The patient's father was eccentric and a dipsomaniac One paternal aunt was well, a second was described as having a bad temper and at one time as having had delirium (about this my notes are confused) A third had hysteria Two cousins, sons of the second paternal aunt, both drank to excess The first paternal aunt had four children, of these, one had a sort of puerperal insanity, from which she recovered Two paternal uncles are said to have of dissipation

The early history of this patient is interesting, as showing the progressive physical descent (*facilis descensus averni*) of such a case Since 2 years of age always more or less out of order, 5 years of age, attacks of nausea, vomiting and headache with fever, delirium alternating with coma, these attacks were followed by excessive weakness, slow recovery from weakness which persisted until the next attack, which occurred at the end of about one month, he lost flesh and his temper became irritable, so that he became violently excited and enraged over little things

Several eminent physicians of New York were consulted One said that he was unable to make a diagnosis A second said it was brain disease, and a third said it was lithemia from the liver Accordingly he was treated for this last with calomel, with the apparent results that after this he had no more attacks but only premonitory signs, which were always stopped by calomel

This perversion of the sexual instinct is the exciting motive of many notorious murders The Whitechapel murderer was undoubtedly the subject of Sadism Similar instances are well known and may be found described in the literature The subject is an important one from a medico legal point of view, as well as of psychologic interest, and it is desirable that the motives leading to crimes of this kind should be thoroughly recognized Lust murders, not murders for the purpose of concealing or committing rape, but violence and murder for the purpose of inducing sexual excitement in the murderer, are probably more common than is generally supposed The sexually exciting element in such cases is the sight or smell of blood, or the cutting, tearing or mutilation of the victim's flesh Verzeni found, as he confessed, unspeakable delight in strangling women, experiencing during the act erections and real sexual pleasure Some find delight in actually eating the flesh or drinking the blood (Leger, Verzeni) Sometimes special pleasure is found in cutting or tearing out the uterus, ovaries and genitalia, which are carried away (Whitechapel murderer), but this is not always the case, and the victims are not mutilated in this respect

A similar perversion is found in the excitement which some have in harmlessly cutting, beating or whipping women and boys A case has been brought to my attention of a man who was in the habit of visiting a prostitute whom he used to strike over the nates with a shingle No coitus was indulged in

PRACTICAL NOTES

Early Symptoms of Diabetes—Unschuld calls attention to an early symptom of diabetes which is seldom mentioned by writers on the subject, but which is yet frequently found, and may assist in an early diagnosis of the affection This symptom consists in cramps in the calves of the legs, and is found in about 26 per cent of all cases The pains occur with especial frequency in the morning upon waking, and occasionally also during the night They are rarely troublesome in the daytime, unless after a nap or a bath Cramps of this nature, occurring in a person in feeble health, should always suggest the necessity of an examination for sugar —*Health*, September 11

Changes in Urine from Medicine—Oleoresins and balsams (copaiba, sandal oil, turpentine and its derivatives) taken as medicines often give a yellowish zone at the circle of contact between the nitric acid and the urine in the cold test for albumin From a ring of albumin, however, this cloud can be easily distinguished by its solubility in alcohol Concerning the test for glucose, many organic medicaments (chloral, chloroform, turpentine, glycerin, salicylic acid, etc) give rise to urinary ingredients which reduce copper solutions to a less or greater degree on prolonged boiling The phenylhydrazin hydrochlorate test will differentiate all these reagents from dextrose Sulphur (or albumin which contains it) gives a black precipitate with Boettger's bismuth test for glucose, and hence must be excluded as a factor if this method be used —*Ed Denver Med Times*, September

Hemol Bromid—The *Medical News*, August 29, quoting Dr Kobert in the *Therapeutishe Wochenschrift*, states that that observer has been seeking to obviate the unpleasant after effects of the inorganic bromids and to that end has "been making trial of an organic bromid which has no injurious effect upon either the blood or digestion It contains only 2 7 per cent of bromin, as against 67 per cent which bromid of potassium contains But only a small portion of the bromin contained in the latter salt exerts any action in the body Holst used bromid of hemol in fifty cases of nervous disease If a rapid effect was looked for, two grams (thirty grains) were given three times a day One half or one third of this dose was employed for a calming effect In epilepsy and hysteria, he obtained no good results where the inorganic bromids have shown themselves efficacious In insomnia, the results were equal to sodium bromid, without any unpleasant sequelæ The conclusion is that bromid of hemol is not capable of replacing inorganic bromids where a rapid effect is desired It is indicated, however, in cases where the sedative and long continued action of bromin is sought for"

Diagnostic Value of Percussion of the Vertebral Column.—Bechterew calls attention to the importance of the results attained by percussion of the sacral region of the spinal cord. He has derived great benefit from it in obscure cases, and urges its general adoption. He describes one traumatic case with symptoms of compression of the cauda equina, plantar, genital and perineal anesthesia, spontaneous pains in the joints, pain on percussion of the sacral region, disturbances in the sphincters, etc., with fever. Percussion of the triangle, whose base corresponds to the upper part of the sacrum and the point to the coccyx, produces in normal conditions a slightly tympanitic resonance. In this case there was a distinctly limited dullness and an operation confirmed exactly the diagnosis as to the seat of the lesion. Caries was disclosed in the serum with a fungus mass compressing the cauda equina.—*Gaz. degli Osp. e delle Clin.*, August 4.

Mechanical Treatment of Sciatic Neuralgia.—Negro of Turin, has cured or materially improved 100 out of 113 severe cases of sciatic neuralgia that had resisted all other treatment, by compressing the nerve. The patient lies flat on his face, the lower limbs touching and stretching to their fullest extent, and the point is found by palpation where the sciatic nerve emerges from the ischiatic notch, which is usually the most painful spot. The right thumb is then pressed on the nerve, reinforced by the left thumb, and the strongest pressure possible exerted for fifteen to twenty seconds, turning the thumb so as to distribute the pressure laterally over as much surface as possible without removing the thumbs. This process is repeated after a minute's rest several times, the pain growing less each time. Five or six of these treatments on successive days produce good results.—*Memorabilien*, August 5.

Formic Aldehyde as a Disinfectant, and Method of Application.—At a meeting of the Maine State Board of Health, Professor Robinson reported that the tests of formic aldehyde which had been made had given very encouraging results. He exhibited to the board the workings of a lamp which he had constructed for its application. The lamp consists of a cylinder into which wood alcohol is continuously fed from a tank similar to that of a German student's lamp. In the top of the cylinder is fitted a diaphragm of copper gauze consisting of two layers, between which is a layer of especial material. Upon the application of gentle heat to the gauze the alcohol below begins to vaporize and change into formic aldehyde, a gas having the germicidal properties of sulphurous acid gas, but in a greater degree. The vaporization progresses as long as alcohol is supplied. Professor Robinson detailed experiments which had been made at the Bowdoin laboratories upon pure cultures of disease germs and upon infected bedding and clothing, by which the germs were quickly killed. Subsequent cultures made from infected articles were found, after exposure of the fabrics to the fumes from the lamp, to have been absolutely sterilized. About a pint of the alcohol, vaporized, would supplant the atmosphere in a room of 3,000 cubic feet.—*Sanitarian*, September.

The Hypnotic Potency of Trional.—In an article which appeared in the *Wiener Medicinische Presse* for April 1 and 8, 1896, and is summarized in the *Wiener Klinische Rundschau* for June 21, Dr. Richard Drews, of Hamburg, remarks upon the frequency with which the physician finds it his chief task to secure for the patient a few hours of quiet sleep, so that he may not only be freed from distress for the time being, but supplied with fresh endurance to battle with the disease. For this purpose a hypnotic is required that is easily taken, that promptly induces restful, dreamless, normal sleep, from which the patient awakes refreshed and strengthened, that is harmless and as free as possible from unpleasant collateral and remote effects, that does not beget a habit, and that can be taken for a long time.

Judging of trional from its action in thirty cases, Dr. Drews thinks it such an ideal hypnotic. Nineteen of the patients were adults and eleven were children. The causes of sleeplessness in the adults were neurasthenia once, hysteria twice, a phlegmon of the hand once, articular rheumatism twice, muscular rheumatism once, sciatica three times, prurigo once, trigeminal neuralgia once, a scald of the foot once, intercostal neuralgia twice, cancer of the uterus once, and pulmonary and laryngeal tuberculosis with severe paroxysms of coughing and profuse sweating at night three times. In the children there were otitis media three times, meningitis with convulsions once, chorea once, night terrors twice, epilepsy once, pneumonia with severe agitation once, and furuncle of the ear once. For the adults, the dose ranged from fifteen to twenty-two grains; for the children, from three to twelve grains, according to the age. It was administered in strict accordance with Goldmann's directions. The adults took it in bed in a cup of hot milk and then drank another cup of milk; the children took it in their evening broth or in a cup of hot tea. In cases accompanied by severe pain twenty-two grains were always given to the adults instead of fifteen grains. In twenty-eight of the cases the result was invariably a restful, calm, natural sleep, coming on in the course of fifteen or twenty minutes, and on the following morning the patients felt refreshed and as well as the nature of the disease admitted of. In two of the cases, that of phlegmon of the hand and that of cancer of the uterus, the hypnotic action was delayed for an hour or an hour and a half, and did *not last for from* six to eight hours, as in the others, but only for three or four hours. Both these patients were sleepy the next morning and complained of oppression in the head, of headache, and of weakness, and the one with uterine cancer suffered also with ringing in the ears and with nausea. These phenomena occurred for several days after each administration of trional, but strict questioning brought out the fact that it had not been taken in the precise manner prescribed.

Treatment of Ozena with the Antidiphtherial Serum.—Drs. Bellfanti and Della Vedova are quoted in the *Medical Week*, May 1, as follows: Bacteriologic examinations made by the authors led to the conclusion that ozena is caused by a microorganism identical in form and cultural peculiarities with Loffler diphtheria bacillus, though differing from it in diminished virulence. The organism was not only found upon the surface but also in the depth of the nasal mucous membrane. According to the authors, it causes the chemic alterations of the secretion, the fetid odor, and the atrophy of the mucous membrane and of the bones. These results led them to undertake the treatment of ozena with diphtheria antitoxin. The results obtained were most remarkable, for of thirty-two patients sixteen were wholly cured, seven almost healed, five rapidly improved, and in only four was improvement slow. Ten c.c. of diphtheria antitoxin was injected every second day or, when possible, every day. The number of injections varied according to the age of the individual, the length of time the disease had existed, and the degree of local and general reaction. On an average 30 c.c. were required to effect a cure. At first the injections caused congestion of the nasal mucous membrane. Soon thereafter the fetid odor disappears, the secretions become liquid, and the formation of crusts ceases permanently. The accidents which compel suspension of the treatment are the same as those observed in the treatment of diphtheria and are without danger.

Report of the Employment of the Toxins of Erysipelas upon Malignant Tumors.—In the *Annals of Surgery* for July is given the minutes of a recent meeting of the New York Surgical Society, a part of which refers to the above subject. At that meeting Dr. L. A. Stimson, Dr. A. G. Gerster and Dr. B. F. Curtis submitted the following report upon the use of toxins in the treatment of malignant disease: "Both before and since our appointment as a committee we have been able to observe, individually and together, a considerable number of cases treated by this means, and in no case have we found any amelioration which held out a prospect of ultimate cure We have, on the contrary, observed in some cases that the rate of growth of the disease was much more rapid during the treatment The treatment also imposes a very severe tax upon the strength of the patient, and apparently hastens the cachexia in most cases We believe that in the instances of apparent cure or marked improvement the correctness of diagnosis is open to doubt We therefore submit 1 That the danger to the patient from this treatment is great 2 Moreover, that the alleged successes are so few and doubtful in character that the most that can be fairly alleged for the present treatment by toxins is that it may offer a very slight chance of amelioration 3 That valuable time has often been lost in operable cases by postponing operation for the sake of giving the method of treatment a trial 4 Finally, and most important, that if the method is to be resorted to at all, it should be confined to the absolutely inoperable cases "

Echinococcus in the Liver Cured by Bacelli's Method —The *Annali di Med Navale*, No 7, describes the case of a sailor brought to the hospital with severe pains in the right flank, fever, dyspnea, insomnia, greatly hypertrophied liver and evidences of a hepatic tumor An exploratory puncture confirmed the diagnosis of echinococcus, as hooks were discovered in the limpid liquid withdrawn, which contained no albumin and very little glucose, but chlorid of sodium in abundance The only question then was whether it was a unilocular or multilocular cyst In the latter case the tumor is usually solid, painful on pressure and knobby, with hypertrophied spleen and a purulent or serous effusion in the peritoneal cavity, with pronounced icterus and intestinal hemorrhages These symptoms were absent in this case and the diagnosis of a unilocular cyst was confirmed by the recovery of the patient Thirty grams of Van Swieten's solution were injected with a Kurschmann syringe and 700 grams of liquid withdrawn The fever ceased the fourth day after this injection Two liters were afterward withdrawn with a Potain needle, which completely emptied the cyst Appetite and sleep returned and the general health slowly improved, the liver subsided to its normal size and the heart and spleen returned to their normal position, but six months passed before the recovery could be considered complete —*Gaz d O e d C* , August 23

Straightening the Spine by Wiring the Spinous Processes Together —Chipault's new method of treating caries of the spine is described in the *Therap Woch* , No 35 The spine is straightened and held in this position by wires that fasten the spinous processes together, so that the orthopedic appliances do not have to contend with the constant tendency to curvature After chloroform the patient is placed on his belly, three quarters pronation, the back turned to the operator A longitudinal opening is then made along the spinous processes, two to three vertebræ above and below the limits of the curvature Without touching the interspinous ligaments both sides of the processes are exposed and the soft parts drawn aside, the assistant at each end then pulls the spine to straighten it as much as possible, and a silver wire is passed through the interspinous ligament above the highest process to be ligated at the bottom near the root The wire is then cut, leaving on each side a piece twice as long as the wound The ligating is done with these two ends, crossing them back and forth and passing them through each interspinous ligament from the highest process downward until the lowest is reached, when the two crossed ends are twisted together The wires must be passed through the ligaments close to the lower edge of the process above to afford as firm a support as possible Each crossing must be tested to see if it is strong and taut before proceeding to the next The soft parts are then sutured without drainage, bandaged and the patient is placed in bed The two difficulties, lateral curvature of the spine and anchylosis of adjoining processes, are met by boring a hole in the processes in the latter case, and in the former by extending the end of the wire on the convex side up to the loop at the top and stretching it tight, which straightens also the lateral curve In cases of lumbar or dorsal caries, the bandage can be changed in five to six days and in cervical caries in ten, and the stitches removed from the soft parts This ligature of the spinous processes is undoubtedly an advance in the treatment of Pott's disease, but it only applies to moderate curvatures of recent origin, that have commenced suddenly and developed rapidly and are capable of reduction in anesthesia, and to weak spines It is not adapted to old curvatures or those involving too many of the vertebræ The presence of an unopened cold abscess or of paralysis is no obstacle Absolute immobilization should follow the operation

Arsenic in Scarlet Fever —A Russian physician, Speransky, announces that he treated a large family of children with arsenic as a preventive measure, when one was attacked with fatal scarlet fever and isolation was impossible Although they slept with the sick one, none of the rest took the disease except the oldest, 18 years, to whom the arsenic had not been administered and the youngest, who had been neglected and had only received occasional doses, with none at all for several days before the disease appeared The arsenic was administered in Fowler's solution, half a drop at each of the two principal meals (8 and 9 years) with half this amount at 3 years When the 3 year old child was taken with the disease he received half a drop three times a day, with powders of phenacetin and terpin hydrate, the 18 year old four drops with the powders The arsenic attenuated the disease in a remarkable manner after it had developed, with no fever after the first day and the child so well that it was impossible to keep it in bed The other cases treated outside showed the same results, a striking improvement in the course of the disease after the first day, with complete recovery in a week The preventive doses were continued for six weeks —*Semaine Médicale*, August 26

Hydatic Cysts of the Liver —Bobroff injects salt solution into the cyst pocket after he has emptied it, to prevent the liquids from the neighboring organs finding their way into it and recommends this process to others In a recent case, after removal of the hyatid and cleansing of the pocket with gauze, he excised a piece 12 centimeters long and injected 250 grams of the salt solution The inverse edges of the pocket were then closed with a double row of sutures and the abdomen closed completely The wounds healed by first intention with only a slight rise in the temperature one day, and the patient left the hospital entirely cured in a month —*Union Méd* , August 15

Hot Water Vaginal Injections —In the treatment of female pelvic diseases by hot water injections Dr J H Burtenshaw gives the following rules for method of application 1 Use a large sized fountain syringe, preferably one holding four quarts, attached to a support three or four feet above the body 2 Always lie upon the back with the hips slightly elevated and the shoulders depressed 3 Use at least three gallons of water as hot as can be borne—*at a temperature of from* 110 to 115 degrees Fahrenheit 4 Take the injection twice daily, morning and evening, except on the two days preceding and the two days following the menstrual flow In cases of chronic leucorrheal discharge in which additional astringent elements, to the douche, are indicated, he adds a tablespoonful of the following mixture to the last quart of water Pulv alum, zinci sulphatis, sodii biboratis, ac carbolici, aa ʒi , aquæ, ʒvj —*N Y Polyclinic*, September

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE, INCLUDING POSTAGE
Per Annum, in Advance $5 00
Single Copies 10 Cents
Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 61 Market Street (Occidental Buildings) Chicago, Illinois

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association Dr Henry P Newman, Venetian Building Chicago Ill, sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL *office*

All communications and manuscript of whatever character intended for publication in the JOURNAL, *should be addressed to the Editor, and all communications relative to the business of the* JOURNAL *proof sheets returned, or in regard to subscriptions, should be addressed to* THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION 61 Market Street (Occidental Buildings), Chicago

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL

INFORMATION WANTED

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL as we have been notified by the postmasters of the larger cities that second class mail matter not having street address would be placed in the general delivery to await call

SATURDAY, OCTOBER 3, 1896

THE MURDER OF THE INNOCENTS

The incidence of mortality in the first years of life is a well-known showing of all tables of vital statistics, but its preventable factors are not so clearly recognized, while far behind lags the resolution to make theoretic knowledge a realized fact Talk as we may about the disadvantages of "grandmotherly government" and "socialistic legislation," no one can affirm that in matters of preventive medicine and hygiene there can be too much governmental oversight The wisdom and morality of the few must become that of the many, and it can only become so by stringently penal legislation and executive control Human nature is at least not yet sufficiently ethical to be allowed indiscriminate and unscrutinized control over the young life that comes to it

Take the matter of child life insurance as an example Is it not evident that parents too poor to bury a child should be held too poor to pay premiums on the insurance of the child's life? And yet this is the excuse constantly made by parents, either sincerely or deceitfully, to justify the custom What a clear temptation to murder[1]

The English medical journals, especially the *Lancet*, have in late years been active in showing up the prevalence of this abuse in England, where it is undoubtedly of greater extent than with us From an editorial in the *Lancet* in 1895 (1 p 428) we learn that of 4,629 children recently subjected to cruel treatment 1,237 were insured Another editorial in the *Lancet* (1895, 1, p 166) on infant neglect, insurance and mortality, among other things says An unfortunate infant, whose death was recently investigated by the coronor for the West Middlesex district, might have been saved by medical aid (which might have been had for a mere pittance), but the parents claimed they were unable to pay a physician anything, yet the insurance premium on the child had been promptly paid up to its death Facts like these sicken the public conscience The *Lancet* calls for drastic reforms, and says the insurance should only be for an amount of the bare cost of the funeral arrangements (which is very cheap in England compared to our funeral rates, we believe) The same editorial urges that evidence of criminal neglect or mismanagement should disqualify parents even for the small sum insured This seems to us very clever, as it shifts the burden and expense of proof on the interested corporation, who would likely be more rigorous in their search for evidence exempting them from payment of the policy than the municipal authorities, ordinarily interested parties

In May, 1895, SIR RICHARD WEBSTER read in the House of Commons a bill providing for the maintenance and encouragement of the mutual benefit principle in such insurance, limiting the sum insured to an average almost as low as that of the friendly societies, £2 ($10) up to 10 years of age This bill also entails upon physicians the duty of inquiring as to the fact of insurance before granting a certificate of death, and a like service is required of the register It allows a child to remain under the protection of this act until 16 years of age The *Lancet* says 'We are aware of no present limitation except the inability to pay the premium, and the average of £4 ($20) and a maximum of more than twice this sum is not uncommon, while payment in some clubs may be made partly in spirits It is significant also that wilful neglect of infants, *according to a recent return*, has been shown to be much more common under the non-mutual *system" (that is, those clubs not organized by workmen for their mutual benefit)* We know nothing relative to the ultimate disposition of this act, and are not aware of any legislation in Great Britain limiting infant insurance According to the *British Medical Journal* (1895, 1, p 291), the reports of the Select Committees on Friendly Societies, 187[illegible] and 1888, contain a large amount of information upon this subject

FRANCIS VACHER (*Lancet*, 1895 1, p 251) suggests that legislation should prohibit all private corporations or individuals from insuring infants' lives, and that the government be empowered to enter into [illegible] will to insure any child free of cost, on p premium at the nearest post office, thus reducing cost of insurance and bringing it directly under the law. Such a measure we do not think necessary or wise, and for us it is, of course, out of the question.

---

[1] In the *Lancet* of April 20 1895 a member of the Massachusetts Society for the Prevention of Cruelty to Children said she found families in which children were deprived of the most ordinary necessities of life while money for the insurance of the dying child was put aside Several other similar instances equally pitiful are given The cost of infant burial is within the reach of thrifty people, and for the rest, in all countries the community is bound to bury when others can not

As to our own country, affairs are in a chaotic state. In 1895 a bill was reported to the Massachusetts legislature providing that no life insurance company shall issue a policy upon the life of any child under 10 years of age, living in that State. The penalty was fixed at $100 for each offence, the law to come into force September 1, 1895. Whether the law ever came to vote or not (probably not in these days of "politics") we do not know, nor whether other States have attempted similar regulation. Medical men in charge of the medical departments of life insurance companies should bestir themselves, both as officers and members of society, to bring about judicious and and needed legislative reform.

Another cause of infant mortality is overlying. It will doubtless surprise even physicians to learn that one thousand children are each year killed in London alone by this careless (or perhaps often intended and criminal) custom. Yet such is the estimate of a London coroner. From an editorial in the *British Medical Journal* (1895, i, 36), we excerpt:

> There are sad sides to a Merry Christmas, and not the least sad of these this year has been the sacrifice of infant life from overlying. On December 27, 1894, Mr Braxton Hicks held five inquests on the bodies of children who had died while sleeping with their parents, the cause of death in the majority of cases being suffocation. The coroner said he could not persuade parents to get cots for their children, and that a thousand infants were overlain in London alone every year. The matter is extremely serious. Perfectly healthy children are sacrificed to the bad habit of making them sleep with their parents. It is perhaps difficult to draw the line and to separate thoughtlessness from carelessness so gross as to be criminal, but Liverpool statistics showing the enormous frequency of deaths from overlying on Saturday night points to the fact that the carelessness is gross, and that unless drink be accepted as a general excuse for crime, the action is in a large proportion of cases criminal. Mr Braxton Hicks announced that he would make it a rule in all future inquests of this character to disallow the expenses of the parents, a course which he adopted in each of the five cases before him. The fight against preventable diseases is hard enough, but it seems harder still to prevent the effects of carelessness and folly.

Of infanticide, every physician is well aware that neither the ancients nor present day savages have a monopoly of the practice. In every city there are men either with or without a medical degree who make a profitable business by murder, through abortion. There are many reasons why these criminals can not be brought within the reach of the law, the principal of course being the inability to secure evidence against them. Their "patients" will not tell, but the evidences of their work are well known to every gynecologist. One thing is, above all things, certain. There should be compulsory inspection and registration of all "stillborn" infants. Braxton Hicks (*British Medical Journal*, 1895, ii, p. 1540) relates an instance illustrative of the ease in which a child may be killed and falsely registered stillborn. The child, plainly a viable one, after being smothered was boldly thrown out into the middle of the road to rot. We would urge upon our general medical associations and societies the duty of promoting such badly needed legislation. They might also profitably institute investigation and control of the disgustingly much-advertised lying-in institutions where "for a consideration," infants after delivery are "supplied with homes."

Undoubtedly it is a difficult matter to educate the community in the care of children and in the value of child-life. The law and a sensitive conscience are agreed that murder of an unborn fetus is as much murder as of one born, and that infant murder is as much murder as is adult murder, but ordinarily the lower classes make an unconscious sliding-scale of criminality increasing in approximation to real murder of the adult, and beginning with conception, when and shortly after, "getting rid of it" is by no means sinful. Against such a tendency in the interest of civilization and ethics we must all protest with what power we may. But the efficacy of our protest will depend upon the numbers that speak, the publicity of the protest, and the effectualizing of it in legislative enactment.

CELEBRATION OF THE INTRODUCTION OF ANESTHETICS

October 17, 1846 a venous tumor of the jaw was removed by Dr Warren without pain, the patient being placed under ether by Wm T G Morton, a Boston dentist, and the next day a fatty tumor was removed, and in a few days, after the performance of some minor operations, Dr Hayward, in the presence of Dr H J Bigelow and others, amputated the thigh of one Alice Mohan, Morton, as before, administering the ether.[1] "From this date," says Lyman, "the success of anesthesia was placed beyond all doubt. The great discovery was immediately heralded throughout the civilized world, and was everywhere adopted with the utmost enthusiasm."

To properly celebrate the semi-centennial of this great discovery, the Massachusetts General Hospital have issued an invitation to a limited number of guests to participate in the ceremonies. We print elsewhere a reduced fac-simile of the card of invitation. It will be noted that nothing in the invitation can be construed into an assertion of priority of use, for the medical public are now well aware that sulphuric ether had been used by inhalation for dentistry and minor surgery by W E Clarke and Crawford W Long, but it was reserved for the Massachusetts General Hospital to have the first capital operation, and to make the world hear. She can then with all propriety and conscious pride celebrate the semi-centennial of

an event that connects her name indissolubly with the greatest boon that has yet been vouchsafed to man

The notable gathering that will be present October 16 in that now famous amphitheater may be warm in their praises and oratory will no doubt be all that the occasion demands, but the larger amphitheater of the world, so far as inhabited by civilized man, will contain thousands of sympathizers with this movement whose sympathy, unwritten and unspoken though it be, will be as sincere and earnest as any May prosperity continue to attend the Massachusetts General Hospital and its staff

PROPOSED LEGISLATION IN REGARD TO EXPERT TESTIMONY

The unsatisfactory conditions that exist in regard to medical expert testimony, have been the subject of a vast amount of earnest thought and their discussion has occupied no inconsiderable space in medical literature but as yet the questions that have been raised seem very far from a satisfactory settlement That they are living questions of the day is sufficiently demonstrated by the contents of the last issue of the Journal, which contained three valuable communications by leading men in our profession together with the equally able discussion that they incited The views there enunciated are certainly worthy of respect and careful consideration, but as the discussion shows, the solutions offered of the actual difficulties are not in all ways acceptable Reform of abuses in medical expert testimony as they exist in our present methods of judicial inquiry is most desirable, but no one seems to have yet discovered the universally applicable cure for these evils

The favorite remedy just now appears to be that embodied in the different legislative proposals that have been put before the law-makers of the three States of New York, Illinois and Minnesota, viz , the appointment of a commission of experts by the judge or judges, either in each particular case or for a given period for all cases This would undoubtedly improve matters, but is open to some very obvious objections One of these is stated by Dr Suiter, the law could not deprive the defendant of his right to call in additional evidence outside of the appointed experts and, if he had accepted these, it might put him in the position of combatting his own witnesses Besides this objection which would occur to a lawyer, there are others equally apparent to a layman or a physician The mere fact stated above that the defendant, say in a criminal case, can not be bound to confine his expert witnesses to the list approved by the judges, leaves open the possibility of nearly or quite all the abuses now complained of His witnesses may be qualified or not, they may be pretentious quacks or they may outweigh as experts all the official appointees There is no assurance that judge-appointed experts will always be really such, judges are fallible, and, as regards medical matters, often ignorant men, they may be influenced by prejudice, friendship, or partisanship, and in the present state of medical practice with the numerous schools not discriminatingly estimated by the laity, the very desire to avoid partisanship might cause a non-medical man or a body of such, to make injudicious or improper selections An official position also, involving public consideration and compensation will be sought after by the unworthy, and too often, it may be, with success

Allowing, however, for these imperfections, such an enactment as that pending in New York State would still do away with many of the objectionable conditions that now exist, and might well be welcomed It creates no real standard, however, for an expert, and in this is its failure The importance of this defect may be variously estimated, but in some respects it is a vital one, and how to avoid it is still a problem for consideration Some provision in the law that no one shall be considered an expert and have his testimony received as such unless he can show that he has had actual experience in and has devoted a certain number of years to the study of the subjects in which he claims to be specially skilled, would perhaps best meet the requirements, and this could be brought in as a part of a bill fixing the minimum compensation for expert testimony by the State This last, in view of some recent judicial utterances, would be an eminently desirable measure as making the State recognize the difference between the giving of opinions which are the expert's stock in trade and ordinary testimony With such a provision in the law, also, we would not have the scandal of specialists in one department testifying as experts in another, a practice which has been unfortunately, to say the least, sometimes indulged in by men of reputation and ability, and otherwise unexceptionable medical practices A jury of laymen is not likely to make distinctions between one man of reputation and another, and the law should not allow them to be misled in this regard by a lawyer's trick, even if men can be found willing to be his instruments At present experts are allowed to estimate themselves and the result is often disastrous to them and to the general standing of expert testimony

Medical expert testimony has probably suffered more from the present defects in the court practice than any other kind, and it is full time for the profession to exert itself in behalf of reform if only for the sake of its own reputation, which continually suffers under the present order of things

"The Atlanta Clinic", Change of Management —With the September issue of that journal, the editor, Dr Edward C Davis, and business manager, Dr W L Champion, retire from control This step has been taken on account of the increased professional business preventing the proper attention to the details of the journalistic work They will be succeeded by Dr Lucien Lofton as editor and Mr Ephraim Smith business manager

CORRESPONDENCE

The Spanish Language and the P -A M Congress

NEW YORK, Sept 23, 1896

To the Editor —Several physicians who think of attending the Second Pan American Medical Congress, to be held in the city of Mexico, if they could secure the services of a well known Spanish speaking physician to act as their guide and general translator, have asked me whether I am willing to go with them in that capacity I replied that I have no objections, but in order that the number of physicians composing the party be still larger will you be so kind as to say a few words about this matter in the JOURNAL?

There are no doubt a large number of professional gentlemen who would willingly go to Mexico, taking advantage of the reduction of the price of the trip for that occasion, if they could find some confrère thoroughly qualified to act as their *cicerone* I remain sincerely yours,

DR A M FERNANDEZ YBARRA

235 Thompson Street

Straw Charcoal with Boric Acid as an Antiseptic

VALLEY CITY, N D , Sept 23, 1896

To the Editor —It may interest some of the JOURNAL readers to know that a mixture composed of one part, by weight, of muslin sifted straw charcoal to two parts of powdered boric acid will heal old ulcers or wounds very rapidly , fresh cut or torn surfaces are healed as if by magic This may be old to many of the profession, but I never heard of it until I used it But even if old it may do no harm to remind all that it is a very valuable combination Fraternally

F H DEVAUX, M D

SOCIETY NEWS

The Central Medical Society of New York —This Society will meet at Rochester, N Y , October 20 Sixteen central counties of the State are represented in the membership of this society, which meets annually, alternating between Buffalo, Syracuse and Rochester

The American Academy of Railway Surgeons —This society, after a very interesting and instructive meeting at Chicago, closed its third annual session September 25 Chicago was chosen as the meeting place for next year The following officers were elected President, L E Lemen, Denver , vice presidents, M C M Gardner of San Francisco, R Ortega of Diaz, Mexico , secretary, D C Bryant, Omaha , treasurer, C B Kibler, Corry, Pa , editor, R Harvey Reed, Columbus, Ohio

Canadian Medical Association —This association has elected the following officers for 1896 97 President, V H Moore, Brockville, Ont , vice presidents For Prince Edward Island, Peter Conroy, Charlottetown , Nova Scotia, J F Black Halifax, New Brunswick, Thos Walker, St John , Quebec, J M Beausoleil, Montreal , Ontario, W W Dickson, Pembroke , Manitoba, R S Thornton, Deloraine , North West Territory, E H C Rouleau, Calgary , British Columbia, E B C Hannington, Victoria , general secretary, F N G Starr, Toronto , treasurer, H B Small, Ottawa The place of meeting in 1897 will be Montreal, in conjunction with meeting of the British Medical Association

The Autopsical Society of Paris —This twenty year old Society, known as La Société d'Autopsie Mutuelle, has grown so rapidly in membership that it now numbers about one hundred Fellows They are nearly all, says the *Medico Surgical Bulletin*, scientists of note, several of whom are women It has for its purpose the placing of the brains of its members at the disposal of surviving members for examination and dissection Fourteen brains, neatly catalogued, are now contained in a glass case at the end of the meeting room, and the fifteenth, which was during life the property of M Abel Havelacque, rector of the Anthropologic Society, now rests immersed in alcohol on the table of the dissecting room, where the man's former associates will meet to weigh, probe, cut and discuss it

Association of Erie Railway Surgeons —The annual meeting was held at Lakewood September 21 An accident occurred at the opening of the session which interfered with the pleasure of the gathering Dr John L Eddy, of Olean, the president of the association, a well known surgeon, stepped into an open elevator shaft and fell to the bottom, a distance of eight feet He was at once removed to his room, where it was found that he had sustained a deep cut across the forehead, a badly sprained ankle and a severely bruised hip On account of this accident to the president, the vice president, Dr Webb J Kelly of Galion, Ohio, presided Dr S Birdsall of Susquehanna, Pa , presented a paper on "Symes ankle joint amputations ," Dr F W Thomas of Marion, Ohio, "Injuries of the throat" , Dr C C Kinnaman of Ashland, Ohio, "Symmetrical gangrene" , Dr C M Daniels of Buffalo, chief surgeon of the Erie Railway, told about his relief and hospital organization scheme, as intended to be adopted by the company Other papers were "Traumatic spinal neurosis," by Dr N R Harnden of Waverly, N Y , "Painful stumps after amputation," by Dr C B Kibler of Corry, Pa , "Railway shock," by Floyd S Crego, of Buffalo , "Clinic review of cases the past year" by Dr Thomas Manley of New York The annual election of officers resulted as follows President, Dr Webb J Kelly, Galion, Ohio , vice president, Dr F W Thomas, Marion, Ohio , secretary and treasurer, Dr W W Appley of Cohocton, N Y

Tri State Medical Society of Alabama, Georgia and Tennessee — The eighth annual meeting will be held in Chattanooga, Oct 13 15, 1896 The following partial list of papers indicates that the session will be of more than usual interest

Convulsions in children treated with large doses of morphin Y L Abernathy, Hill City, Tenn

The therapy of antipyretics P L Brouillette, Huntsville, Ala

Cystitis , report of cases D S Middleton, Rising Fawn, Ga

A new splint for fractures below the surgical neck G A Baxter, Chattanooga

Humphrey's operation (amputation of the penis) with presentation of patient Cooper Holtzclaw, Chattanooga

Diseases of the veru montanum (caput gallinaginis) W Frank Glenn, Nashville

Acute pelvic congestion Valentine Taliaferro, Atlanta

Operations for abscess of the liver W C Townes, Chattanooga

Treatment of pus in the pelvis W E B Davis, Birmingham

Some remarks on syphilis W F Westmoreland, Atlanta

Observations on the treatment of specific and non specific venereal ulcers Wm S Goldsmith, Atlanta

Bacteriologic data in the drainage of the peritoneal cavity George S Brown, Birmingham

A statistical report of some of the more recent remedies used in the treatment of tuberculosis, and summary of recent preventive methods of value R. H Hayes, Union Springs, Ala

The Turkish bath , its therapeutic indications Louise Eleanor Smith, Chattanooga

Microscopic and chemic aids to diagnosis Katherine R Collins, Atlanta

Vaginal hysterectomy for bilateral suppurative processes of the uterine adnexa W D Haggard, Jr , Nashville

Some obstetric complications with report of cases R R Kime, Atlanta

Puerperal eclampsia Searle Harris, Union Springs, Ala

Puerperal eclampsia J E George, Rockwood, Tenn

Medicine , Hippocratic and operatic John P Stewart, Attalla, Ala

Diseases and treatment of the accessory sinuses of the nose B F Travis Chattanooga

Report of a case of bradycardia W C Bilbro, Murfreesboro

Paper on diseases of the eye J M **Crawford,** Atlanta

Paper on diseases of the eye Alec Sterling, Atlanta
The Woodbridge treatment of typhoid fever J W Duncan, Atlanta
Treatment of cancer of the skin C R Achison, Nashville
President's address, the Doctor of Medicine J B Murfree, Murfreesboro, Tenn

College of Physicians of Philadelphia—SECTION ON OPHTHALMOLOGY —A meeting of the section was held March 17, 1896, Dr Wm F Norris, chairman, presiding

Dr George C Harlan exhibited a case of traumatic enophthalmia in a boy 5 years old, who five months previously was wounded by the horn of a bull The right cheek and temple and the lower eyelid were lacerated, and the inferior margin of the orbit was chipped There was complete ptosis At the time of examination the tendo oculi was found to have been torn away and the lower lid was dragged downward and outward by the action of the orbicularis and the contraction of the cicatrix The surgeon who attended the patient at the time of the accident reported that there was considerable orbital cellulitis with abundant discharge of pus from between the lids, but there never was exophthalmia He thought that the cellulitis was confined to the lower part of the orbit At present the eyeball is retracted and has the appearance of being very much smaller than its fellow The cornea is situated five millimeters behind the plane of that of the other eye There is scarcely more ptosis than would result from the depression and loss of support of the lid When the patient looks directly forward the palpebral fissure is five or six millimeters wide He insists that he sees well with the eye Though the movements of the eyeball are much restricted no diplopia can be detected There is complete inability to look upward beyond the horizontal line either directly or to the right or left Horizontal movements are normal and the downward excursion is much exaggerated

Dr Charles A Oliver gave the clinical history of a case of ciliary staphyloma and excavation of the optic disc following traumatic cataract in a boy 4 years old The clinical picture of this case of complicated secondary glaucoma was complete Unlike similar cases of sudden obstruction to proper lymph stream circulation, there remained from the very first, as shown by the fields of vision, and as afterward proven ophthalmoscopically, an element that may possibly complicate many more cases of the traumatic type of this disease than is at present imagined, and that is retinal detachment Again, the condition of the vitreous and its peculiarity of opacities, taken in connection with the history of the case, would tend to show that there was a hemorrhage into that humor which probably might have been recognized ophthalmoscopically had the patient been seen a week earlier These, with a few certain evidences of a low grade iridocyclitis, made the case still more atypical On the other hand, the progressive diminution of the field of vision, the gradual distension of the globe and the localized tissue bulgings in the upper ciliary regions, the deep and characteristic cupping of the nerve head, the reapproximation of the remaining areas of retinal detachment, and the late, fixedly increased intraocular tension all show the certainty of degeneration even in a young and yielding eyeball when such tissues are subjected to a persisting increased intraocular pressure The case illustrates the results of two conflicting contemporaneous conditions produced by traumatism localized inflammatory reaction and obstruction of lymph stream circulation

Dr George E de Schweinitz presented a "Further note on an unusual form of macular lesion following iritis" The patient, a woman 50 years old, recovered with a nearly normal sharpness of vision, but with some vitreous opacities from a violent attack of serous iritis The eye remained comfortable for eight months, when she appeared with a positive scotoma and the ability to see to count fingers only when situated in the periphery of the visual field In addition to the positive scotoma which the patient described as appearing "like a dinner plate with a green edge," there was a small absolute scotoma about the horizontal level Ophthalmoscopic examination revealed an oval reddish area, giving the impression of a disintegrating hemorrhage and containing in the center several white dots situated exactly in the center of the macular region Dr de Schweinitz referred to the unusually distinct macular ring which seemed to indicate that there must be some thickening in the periphery of the hemorrhagic area

Dr Oliver exhibited a water color sketch of a case of unusual submacular hemorrhage forming a part of some very curious lymph extravasations in the retina without any vitreous disturbances, found in the left eye of a healthy woman 65 years old, from whose eye he had successfully removed a black cataract by simple extraction about two months previously

Dr de Schweinitz gave the clinic history of a patient suffering from convergent strabismus of the left eye and a very high myopia 16 D Ophthalmoscopically, the following lesions were presented A small posterior polar cataract, numerous fine vitreous opacities, and a horizontally oval optic disc, of a greenish gray color The nerve head was imbedded in the center of a huge mass of opaque fibers which followed the course of the principal vessels almost to the periphery of the eye ground, in all directions, but less markedly downward and to the nasal side A small patch in the macular region was not covered by the opaque fibers, but was disturbed by superficial choroidal changes There was almost complete loss of nasal field, and of the entire center of the visual field, with exception of a small area to the nasal side of fixation, about 10 degrees in diameter, within which the white test object was dimly seen Colors were correctly appreciated when held in the temporal field

In the discussion, Dr B Alexander Randall showed a card-specimen of a case of retained nerve sheaths in a case that had been sent to him for supposed intracranial disturbances In this case there was an isolated patch situated in the macular region Dr Oliver exhibited the drawing of a case in which the medullation began at the edge of the disc and divided into two comet like processes extending along the lines of the larger retinal vessels

Dr James Thorington, by invitation, exhibited an asbestos cover chimney with disc attachment for ophthalmoscopic purposes The original form with the disc attachment he had made two years previously The present arrangement showed that five changes could be made in the disc 1 The one centimeter opening fulfilled all the purposes of the original chimney 2 The two centimeter opening permitted greater freedom of movement on the part of the observer, without moving the light 3 The three centimeter opening may be used as a source of light for the concave skiascope, or for the ophthalmoscope, otoscope, etc 4 A round section of cobalt blue glass for the chromatic aberration test of ametropia had been added, as likewise 5 The perforated disc with perforations and spaces each 1 45 millimeter to test for astigmatism at one meter's distance

Dr Thorington showed a new form of perimetric lenses which received its name from the fact that their optical center corresponds to the points of fixation in the fields of vision The reasons given for the recommendation of the lens, were, that it gives to the eye that form of lens which is consistent with a normal form of the visual field, it removes the edge of the lens to a sufficient distance so that the edge can not be seen to any great degree while the eye is fixed straight ahead, and that bifocal segments can be made much larger He stated that the increase in weight need rarely exceed the ordinary form, twenty five to thirty grains, the large size does not attract much attention, and the cost will remain the same as in the ordinary styles used Upon account of necessary greater weight and thickness, he believed that this form of lens can not be used for cases of aphakia and high myopia, but showed that as this class of cases constitutes much less than one half of all refraction cases (37 per cent), the lens will be accepted in the majority of instances

Dr Oliver exhibited and demonstrated a series of microscopic specimens showing the various forms of eyes seen in fish, reptiles, birds, quadrupeds, and man He showed the marked differences in the conditions of the dioptric media, the varying shapes of the eye ball, the relative positions of the eye in the head of the animal, the adaptations for near and for far focusing the arrangements for increase of the interior illumination, the positions and peculiarities of the nerve structure, and the relationship existing intra cranially between the two organs, in the aquatic, the terrestrial and the aerial forms of animal life

PUBLIC HEALTH

California's Mortality Report for August—Reports from fifty cities, towns, villages and sanitary districts, aggregating a population of 739,132, show a mortality of 865—a death rate of 1 17 per thousand for August, 1896, or 14 04 per 1,000 per annum

Isolation of Lepers in Russia—A "leprosorium" has just been completed at Wenden, and Virchow congratulating the Society for the Prevention of Leprosy during his recent visit to Russia, remarked that they had accomplished in this isolation of the lepers more than the most powerful of the popes had been able to effect in the days of their greatest supremacy

Horse meat Consumption in Paris—There are at least two hundred horse butcher shops in Paris The first one dates from July 1, 1866, since when the consumption has grown continuously In 1872, 5,034 horses were eaten in Paris, in 1878, 10,000, in 1894, 21,227, in 1895, more than 30,000

Mortality Report of Connecticut for August—There were 1,644 deaths reported during the month of August This was 33 more than in July, and 293 more than the average number of deaths in August for the five years preceding the present The death rate was 23 6 for the large towns for the small towns 21 6 and for the whole State 23

Typhoid Fever in the Navy—Surgeon C A Siegfried, of the battleship *Massachusetts*, reports that on August 31 he was compelled to transfer from the vessel to the Brooklyn Naval Hospital the fifth case of typhoid fever that had occurred aboard since she was commissioned at League Island in June last The surgeon is reported as saying that he attributes the disease to the bad drainage of Philadelphia, and the condition of that part of the city nearest League Island

Quarantine Station for Northern New Jersey—Dr A H Doty, Health Officer of the Port of New York, has applied, through Dr H C Herold, the Health Officer of Newark, to Governor Griggs of New Jersey, for the establishment of a quarantine station at Perth Amboy While all vessels that come to New York are obliged to stop at the boarding station of the quarantine office on Staten Island, they can land at Perth Amboy without interference, and there is therefore danger of contagious disease being spread from that point Governor Griggs, it is reported, will recommend such a health station in his next annual message to the Legislature In the meanwhile he has promised to use a $10,000 emergency fund which is at his disposal for the suppression of any outbreak of disease, should the occasion arise

A Society for the Prevention of Noise—The formation of such a society is suggested in the *North American Review* by Dr J H Girdner He contends that there is as rightful need for such a society as for the Society for the Prevention of Cruelty to Children It is, indeed, for the prevention of cruelty to grown people The continued concussion of noise on the auditory nerve is injurious to the whole nervous system, and is a great contributing element to the nervous prostration so common among city dwellers It is a well known fact that one coming from the country is almost stupefied by the multitude of sounds in a great city The city man is used to it, but it is at the expense of vital force, and he undergoes, unconsciously a strain that is great and wearing Dr Girdner's view is that a man has as much right to legal protection against an assault on his auditory nerves by useless noises as he has against an assault on his nerves of touch, by being whipped or beaten in any way

Improvements at the New York Quarantine—Dr A H Doty health officer of the port of New York, is commended by the *Medical News*, August 29, for the great degree of efficiency that has signalized his tenure of office One of his innovations is the wearing of a uniform by himself and his deputies when they are "on duty" The uniform is a badge of authority especially impressive, normally so we might say upon the foreign element that visit these shores for the first time New headquarters are in course of construction, a part of which will be devoted to a bacteriologic laboratory This laboratory is already fully equipped and ready at a moment's notice to undertake the diagnostic confirmation of suspicious cases, so that a few hours of delay, while the investigation is being made, enables the health officer to determine on a scientific basis, whether a ship must be detained at quarantine or be allowed to proceed "This fact is not usually appreciated by the general public, and the solution of this question of delay by the present health officer certainly reflects the greatest credit upon him If a ship arrives after sundown, instead of being obliged to lie at anchor for the night in the lower bay, she is inspected at once and allowed, if in a suitable condition, to proceed to her berth If there are immigrants or others requiring individual inspection, an electric search light is set up upon the deck, and under its powerful beams the inspection is satisfactorily accomplished If the passengers or cargo require disinfection, the boat, which the health officer has just had constructed, will accomplish it *tuto, cito et jucunde* A row of bathrooms on either side of the boat will quickly disinfect eight persons by spray or vapor, or both Clothing, bedding, etc , is all disinfected by steam, *in vacuo*, in a great car, such as is in use by the city Board of Health The cargo itself is disinfected by sulphur gas, which is carried from the disinfecting boat in pipes under pressure, and distributed where needed, as water is distributed with hose Thus, a ship, her cargo and her crew, coming from an infected port could, in a few hours, be sent into the harbor with a clean bill of health, the safety of the public being assured and the rights of the shipping master protected as well Surely this is a prodigious advance over old methods Should a ship come to our shores, containing many cases of infectious disease—cholera, for example—there would be no long and vexatious detention of the well and clean, together with the sick The former, after disinfection, would go on their way, and for the latter the health officer has provided large and commodious barges anchored near the quarantine islands, isolation being thus complete and the conditions as favorable as possible for recovery It is to be hoped that this system may not require the severe test of experience, but if it should we see no reason to doubt its efficiency If successful, it would redound primarily to the great credit and praise of the present health officer it would also be a demonstration to the public that its safety in sanitary matters depends largely upon the endorsement and support of the medical profession "

Typhoid Fever at Albany, N Y—The *Bulletin* of the North Carolina Board of Health, August, gives a resume of some recent studies on the s[illegible] Good [illegible] The writer takes for an object [illegible] stat[illegible] that

Albany, N Y, a city whose water supply is taken from the contaminated Hudson River He quotes the statements of Professor Mason of the neighbouring city, Troy, to show the economy that might be exercised by officials in curtailing the expense account inevitably incident by that water borne zymotic disease, typhoid fever What is the tax levied annually by that fever upon a city of 100,000, for instance Albany, N Y From statistics given in the five last annual reports of the State Board of Health, the deaths due to typhoid fever in Albany average 75 for the year Rating the money value of each life at $2,000 this death rate would mean an annual pecuniary loss to the city of $150,000 Funeral expenses are variously estimated at from $20 to $30 Should we accept the intermediate value of $25, this item would cause $1,875 to be added to the above sum, thus raising the total direct loss through death to $151,875 But typhoid fever does not always kill, its mortality rate is commonly quoted at about 10 per cent For the present purposes should we assume nine recoveries for each death from the disease, and place forty three days as the period of convalescence (the average of 500 cases at the Pennsylvania Hospital), we should have a term of 29,025 days as representing the time lost, per year, by the 675 persons who have the fever and recover Thus an annual loss of over seventy nine years has to be borne by the city's capital of productive labor This great amount of enforced idleness, when translated into money value, should very properly be added to the death loss above estimated Fixing the rate of wages at $1 per individual per day, a very low figure, considering that the bulk of typhoid patients are in the very prime of life, there is a loss of $43 for wages for each recovery, or a total yearly loss for the city from this item of $29,025 The cost of nursing and doctors' bills equals at least $25 per case, which is a very low estimate, thus adding the further amount of $16,875 to the gross sum Expressed in tabular form, this yearly tax imposed by typhoid fever in Albany is given and, upon a most conservative estimate, it is practically $200,000, which is $2 a year for each man, woman and child in the city, or a yearly tax of $10 for every family of five persons 75 deaths at $2,000 each, $150,000, 75 funerals at $25 each, $1,875, wages of 675 convalescents, during 43 days, at $1 per day, $29,025, nursing and doctors' bills for 675 convalescents, at $25 each case, $16,875, total tax levied annually by typhoid fever upon the city of Albany, $197,775 It can readily be seen that public works which could eliminate a reasonable fraction of this great tax would pay for themselves in the course of a few years, even though they were originally expensive Finally, it is right to inquire what fraction of the present typhoid loss it would be reasonable to hope to save if pure water should be served in the city in place of its present polluted supply To answer this question, recourse must be had to statistics obtained from other cities, covering periods before and after better water systems had been introduced Such data have been already given for a number of cities and communities, and it only remains to anticipate what will be later said of Munich, and state that improved water and sewerage have reduced the annual typhoid mortality from an average of 25 4 per 100,000 to 2 7 Surely pure water pays in a city with such a record, and likewise it would pay in the newer but growing cities on this side of the Atlantic Americans insist upon being supplied with much more water per capita than is usually furnished for Europe, but they are singularly indifferent as to its quality It would be a reform of great moment if they could be induced to curtail the present enormous waste of public water, such as that of Buffalo, for instance, which is stated to be 70 per cent of the entire pumpage, and to spend the money thus permitted to leak away in a vigorous effort to improve the quality of the water No such lowering of the typhoid death rate as occurred in Munich, San Remo and sundry other places, could be looked for, perhaps, but a large percentage of the present rate could be cut off, and we think, from a consideration of the above figures, that such a reduction would pay No weight should be attached to the argument, so often advanced by the individual householder, that he and his family have used the water without evil results for the past fifty years A single family is too small a collection of units upon which to base any estimate touching the question at issue Placing the typhoid death rate for Albany, as above, at 75 annually, it would call for one death in a family of five persons every 261 years, a period much beyond the limit of ordinary family record "

Vaccination in London Neglected, the Gloucester Epidemic Stamped Out —From the parliamentary intelligence reported in the London *Lancet* of August 22, we learn that in Gloucester, during the thirty weeks ending July 25, there were notified 2,008 cases of smallpox That journal further states that "Gloucester seems to have got rid of the disease and to be able to chronicle a clean sheet so far as smallpox is concerned, after suffering 2,000 attacks within a period of about ten months The bitter lesson taught by this epidemic is not likely apparently to stem the tide of opposition to vaccination wherever antivaccinationists congregate Proof of this has been seen quite recently in the parish of Islington, in the different attitude of the vestry, who, as a health body, are desirous of seeing the vaccination acts enforced, and of the so called vaccination authority, to wit, the poor law guardians, who are wilfully ignoring the voice of the vestry, not only so, but the guardians also decline to hear what the public sanitary officers of the parish have to say on the health side of the question The only consolation to be derived is to suppose that the reign of the poor law administrators is probably short lived now, and the sooner the bodies charged with safeguarding the public health have a voice in the matter the better will it be for all concerned " In another paragraph the same journal makes the following reference to to the closing up of the epidemic at Gloucester, and to the expenses borne by its citizens on account of that epidemic "The Gloucester sanitary committee have, it appears, discontinued the issue of weekly statements as to smallpox occurrences, the health of the city being deemed to approximate now to its normal condition It would seem that the expenses connected with the recent epidemic, so far as the guardians are concerned, have been about $10,280, and that it has been decided to ask the local government board to sanction the raising of a loan to meet the case It will be interesting to know what is the sum total to which the citizens will have to subscribe in respect of the epidemic in all its bearings The expenses appearing on the books of the town council will, however, we imagine, go but a very little way toward the whole, as the amount of money which must of necessity have been expended in one way and another by the public in matters of a personal character but having direct relation with the prevalence of smallpox in the town, must have been excessive We know that charitable contributions were made with a liberal hand "

A Less Stringent Quarantine for Diphtheria —The *Archives of Pediatrics*, in an editorial paragraph, commends the considerate courage of the New York City Board of Health in adopting a change, not of the highest moment but of importance as indicating a spirit of concession The regulations have been by some considered unduly harsh and arbitrary and as trenching upon the patient's personal liberty It further says

"There was a growing tendency to postpone the sending of cultures through the fear that patients who might suffer from very mild attacks of diphtheria might be made prisoners for days or weeks after every symptom of disease had disappeared That experience is not a pleasant one to the family physician It was questioned whether the board of health was warranted in depriving citizens of their liberty unless they were able to say that the bacilli discovered in the throat, weeks after an attack of diphtheria, were virulent It seemed doubtful to many men of large experience whether the scientific evidence yet available warranted such rigid measures The present regulations will certainly commend themselves to the practitioner They prohibit any person known to have Loffler bacilli on their mucous membranes from attending school or mingling in other public assemblies where innocent and unsuspecting persons may become infected Provision is made for informing every family in which diphtheria occurs regarding the method of its propagation and the dangers which may follow from contact with those who are known to carry the germs in their throats This knowledge having been furnished the patient and the attending physician are privileged, under certain limitations, to assume any responsibility and risk which may arise from the violation of quarantine This action is unquestionably wise It removes the chief objection which has been raised against sending cultures to the board of health It will undoubtedly encourage the earlier sending of cultures, and hence the earlier and more accurate diagnosis of diphtheria and would seem to sufficiently guard the public interest The endeavor made during recent years by the Board of Health of New York to aid the physicians of the city in their battle against disease can not be too highly commended The willingness also exhibited to correct errors and to render necessary regulations as little irksome as possible, is worthy of equal commendation "

Sanitary Rules for Schools in Indiana —The Indiana State Board of Health has issued the following letter of explanation in relation to the opening of the public schools for the fall term

"Simultaneously with the annual opening of the public school, diphtheria, measles, mumps, scarlet fever and many other diseases usually increase This is caused by the congregating of the pupils They mass together and contact spreads infection Some few pupils may have just recovered from a communicable disease, or they may be from families that have been smitten and, being infected, they transmit disease to those who are susceptible It is reasonable to assume that the suddenly imposed confinement in the school after a period of freedom frets the children for a few days, causing more or less nervousness and so resistance is temporarily lowered In this way susceptibility may be increased, and sickness may more readily follow To do all that is possible to prevent the usual school opening increase in illness is the object of these rules

"It is ordered in the rules that desk tops and banisters be washed with soap and water and afterward treated with a disinfectant This is required because it is more probable that disease germs are planted upon exposed desk tops and banisters by infected persons, and being transferred by the children's hands to their mouths, disease results The washing and disinfecting will do much to prevent infection from this source

"Open water buckets and large tin cups are condemned because the dipping of water with cups, which are used by many, introduce spittle into the supply, and beside, open buckets catch dust and dirt Diphtheria, diarrhea, sore mouth and other complaints have been transmitted in this way This source of disease may be avoided to a considerable degree by supplying a covered tank with a large, free flowing faucet and a small cup The opening of a large faucet will furnish a strong stream, which will suddenly fill the cup and wash the saliva from the edge Ample drainage must be provided for carrying away the waste water

"Slates are condemned because of their uncleanliness Writing and figures being obliterated as they frequently are, with spittle, and as the damp slates readily collect dust, the danger of transmission of disease in this way is very great Small children generally place pencils and pens in their mouths, and if these articles are promiscuously distributed without being sterilized, as the rules direct, infection may result The collection of pencils seems necessary to always insure one to each pupil

"Spitting is prohibited because it is a possible source of disease is filthy and is unnecessary

"These rules may seem trifling and unnecessary to those who have not given consideration to modern sanitation, but the teachers more than any other public officer may secure the physical well being of the pupils as well as the intellectual advancement

"It is hoped that all the school authorities of the State will promptly enforce these rules

"Douglas C Ramsey, M D , President

"J N Hurty, M D , Secretary "

COPY OF RULES ISSUED

Rule 1 All teachers of public, private and parochial schools, all county, city and town health officers and all school authorities shall refuse admittance to the schools under their jurisdiction of any person from any household where contagious disease exists, or any person affected with any evident or apparent communicable disease, or any person who may recently have been affected with diphtheria, membranous croup, scarlet fever, whooping cough, contagious skin disease, measles or other communicable disease, until first presenting a certificate signed by a reputable physician stating that danger of communicating such disease is past and said certificate is approved and indorsed by the health officer in whose jurisdiction the person may reside

Rule 2 All teachers of public, private or parochial schools shall refuse admittance to their schools of filthy or unclean persons

Rule 3 All school commissioners school trustees in cities and towns and township trustees shall have the school houses under their control put in sanitary condition before school is opened and kept so throughout the year Floors shall be scrubbed, windows cleaned, desks and all woodwork washed with soap and water and treated with a disinfectant Windows shall be in repair, so that ventilation may be made perfect Heating apparatus shall be efficient and in good order and dirty walls and banisters made clean Banisters and tops of desks shall be washed with soap and water and treated with a disinfectent once each week

Note The disinfectant for treating desk tops, banisters, etc , and for use in urinals and closets may be cheaply made by the following formula and kept on hand in any quantity desired To make ten gallons Chlorinated lime, 40 ounces, soft water, 10 gallons Thoroughly stir together and let stand until clear The undissolved lime will fall to the bottom and the clear supernatant liquid may be used on the desks, banisters, baseboards etc The fresh milky mixture, as well as the creamy sediment may be used in urinals, closets and sinks This disinfectant is not poisonous or dangerous Chlorid of lime of the best quality may be purchased in quantity for 5 cents per pound The cost of the disinfectant is, therefore, less than 2 cents per gallon The use of all patent or secret disinfectants is discouraged by the State board of health

Rule 4 School commissioners, school trustees in cities and towns and township trustees shall provide small drinking cups not to hold over a gill Buckets or pails to dip from are condemned, and reservoirs or tanks of ample size having large, easy acting, free flowing faucets shall be provided When water is drawn direct from public water pipes or pumps reservoirs or tanks are not required Ample drainage facilities for waste water shall be provided and the pupils directed to allow the cups to flow over when water is drawn Drinking cups shall be cleaned and sterilized daily

Rule 5 Slates are condemned Paper tablets or pads shall be used instead Riveted metal boxes of tin or galvanized iron with hinged covers and of proper size shall be provided for each school room These are to receive pens or pencils, which must be collected from the children each day, and shall not again be distributed until box and all have been sterilized by heating in an oven at or above boiling heat for one half hour School commissioners and school trustees in cities and towns and township trustees are directed to enforce this rule

Rule 6 Heating and ventilating shall be looked after with great care Every school room shall be provided with a thermometer and a temperature not exceeding 75 degrees Fahrenheit nor less than 65 degrees be maintained during school hours School commissioners, school trustees in cities and towns and township trustees are directed to enforce this rule

Rule 7 Janitors when sweeping shall use damp sawdust or slightly sprinkle in order to prevent dust Dusting shall be done with damp cloths School commissioners, school trustees in cities and towns and township trustees are directed to enforce this rule

Rule 8 The water supply shall be pure and wholesome and closet or privy facilities shall be unobjectionable School commissioners, school trustees in cities and towns and township trustees are directed to enforce this rule

Rule 9 Spitting on the floor of any school building is absolutely forbidden Teachers and all school authorities are directed to enforce this rule

Douglas C Ramsey M D , President

J N Hurty, M D , Secretary

NECROLOGY

William Turner Wooton, M D (Department of Medicine, University of Pennsylvania Philadelphia 1846) at Frederick Md , September 14, aged 74 years He was member of an old and distinguished Maryland family, was born in Montgomery County, but had practiced medicine in Frederick nearly all his life Dr Wooton was a frequent contributor to leading medical journals

John Lawrence Dawson, M D, at Charleston, S C, September 17 He was born at the celebrated Mitkin plantation, near Monck's Corner, in 1815 Was the son of Lawrence Monck Dawson and grandson of a daughter of Lord Proprietor Monck He graduated from the Medical College of the State of South Carolina, Charleston, in 1836

After leaving the Medical College Dr Dawson went to Paris with Dr Chazal and spent some time studying and visiting the hospitals Returning to South Carolina he located in Summerville After a year or two, however, Dr Dawson returned to Charleston For some years he was United States physician to the Arsenal garrison, city registrar and health officer, holding the offices simultaneously It was during his occupancy of these positions, in about 1840, when with the late Dr Henry W DeSaussure, he brought out the census of Charleston, which has been used as a standard authority since Dr Dawson joined the State Medical Society in 1837 and was prominent in its deliberations He was a member of the standing committee, and also treasurer of the Society for the relief of the Families of the Diseased and Disabled Indigent Members of the Medical Profession of the State of South Carolina, an organization of which he was one of the founders

P F Beverly, M D, at one time President of the Ohio State Medical Society, at Columbus, Ohio, September 18 from a stroke of paralysis, the third one in a year Dr Beverly was 69 years of age, and a graduate of Starling Medical College, Columbus, Ohio

Charles Bernacki, M D, of New York City, at Schandau, a Saxon watering place, September 17, aged 84 years He was born at Starascol, Galicia, studied medicine in the University of Vienna and, after some practice in military hospitals in Australian Poland, opened an office in Vienna After the political disturbances of 1848 he fled to America From 1846 he was medical director of the Germania Life Insurance Co

J C Sackville, M D, of Washington, Pa, aged 82 He was struck by a Baltimore and Ohio train September 23, and instantly killed Dr Sackville was a cousin of Lord Sackville West, formerly English ambassador at Washington, D C, and a brother in law of the English poet, Robert Carr Foster He graduated from the Royal College of Surgeons, London, England, in 1838

Edward Benkendorff, M D (Medical Department, Washington University, St Louis, Mo, 1847) He was a native of Prussia A relative of the same name is lord chamberlain to the czar

H H Hunt, M D, at Independence, Iowa, September 25, aged 72 years He was county coroner for thirty years and was also a surgeon in the late war

William H Perkins, M D, Long Island College Hospital, Brooklyn, N Y, at Hancock, Md, September 11 ——P S McArthur, M D, Geneva Medical College, Geneva, N Y, 1847, at La Crosse, Wis, September 19, aged 74 years

MISCELLANY

Treasurer's Notice —The Treasurer has received $5 00 in currency from Buffalo, N Y, which he will properly credit if the remitter will send in his name with date of remittance

Dartmouth Medical College —William Thayer Smith, M D, of Hanover, N H, has been appointed dean of Dartmouth Medical College, to fill the place of the late Dr Carleton P Frost Dr Smith has been professor of physiology for a number of years Prof Gilman Frost has been appointed secretary and treasurer

Professor Virchow's Birthday —A cablegram states that great preparations are being made for the birthday of Professor Virchow, which occurs October 13 Scientists from all parts of the world, including the United States, will be present with gifts and congratulations

Mutilation of Prisoners in Abyssinia —The Italian government recently sent an artificial limb maker to Africa to supply hands and feet to about two hundred and fifty native soldiers who had been captured by the Abyssinians and, after having each a foot and a hand cut off, were set free again, but the unfortunates who have been evirated can find no instrument maker to come to their relief Eviration is a cruelty much practiced by the Abyssinians on their Italian prisoners

International Scientific Language —In letter a written before his death by Prof Billroth to Dr Jankau he remarks I recommend the simplest of the Latin languages, Spanish, for an international scientific language after this would come Italian and French, and among the Germanic tongues, English alone English might even be preferable to all others, as it is one of the simplest But as the Latin races have no aptitude for acquiring foreign tongues, it is necessary on account of their great talents in scientific matters, to make this concession to them, and select one of the Latin tongues for the international language —*Gaz Méd de Paris*, August 29

Toxicity of Gastric Juice in Epileptics —Agostini has found that the gastric juice from an epileptic injected into the abdomen of a rabbit proves fatal with general toxic and clonic convulsions, especially if withdrawn immediately before or after an attack Gastric juice from a normal person injected in the same way does not produce any evil effects He considers these facts a valuable indication for the successful therapeutic treatment of epilepsy, with systematic rinsing of the stomach, disinfection of the intestines, etc He found that the toxicity was diminished by the administration of bromids —*Cbl f Phys*, August 22

An Ancient Russian Superstition —A fatal case arising out of the widespread superstition that a candle made from human fat bestows invisibility upon its possessor, is reported from Ostrogozhsk Two Russian thieves of the district were so firmly persuaded of the truth of this that they murdered a youth of their village in order to procure the candles in question Having cut open the body, they removed the fat surrounding the kidneys, and, placing it in a tin box, took it home There they proceeded to melt the fat over the fire Unluckily for them an old woman, their housekeeper, became suspicious and informed the authorities Her statement, coupled with the mysterious disappearance of the youth, who was a handsome and a popular young fellow of 18, led to the prompt arrest of the ruffians and their ultimate trial for the murder The body was discovered, and the portions lacking therefrom lent further confirmation to the crime

Can Commit to Insane Asylum —The supreme court of Louisiana holds, in the case of State v Uniake, decided June 30, 1896, that where a party has been indicted, and his counsel suggests his insanity, before trial, and a commission is appointed to inquire into his mental condition, and reports him to be insane, and the jury returns a verdict accordingly, and the judge of the criminal district court remands him to the parish prison, without a commitment to the insane asylum, the judge of the civil district court has authority, under section 1768, Revised Statutes, to inquire into the facts and circumstances of the case, and if, in his opinion, he is dangerous to the citizens and the peace of the State, to commit him to the insane asylum of the State

Right to Have Examination made by Female Physician —Under the provision of the New York Code that if a female plaintiff be subjected to a physical examination she shall have the right to have such examination made by a female physician, a decision was called attention to in the Journal of June 20, page 1245, to the effect that the fact that the order compels her to submit to an examination by a physician not of her own sex, is not a ground for the vacation of the order, she not having made any effort to have the order modified. But the appellate term of the supreme court of New York, first department, takes a different view of it, as its decision of July 27, 1896, in Lawrence v. Samuels, shows. It holds that the provision in question is for the protection of female suitors, and that the plaintiff in this case was entitled, as of right, to have inserted in the order the provision that a female physician make the examination, without making any special application for it as a favor or privilege, and that, in so far as the order appealed from a male physician named, it must be reversed, with liberty to the defendant to apply to the court below for the naming of such a physician as the Code authorizes.

Effect of the X Ray on the Skin.—We have seen it clearly demonstrated that the ray has an effect upon the skin, but only after frequent and long exposure to its influence. The appearance of the skin strongly resembles severe sunburn, with the accompanying pain, swelling, blistering and discoloration. The congestion in the hand is very marked, and the hand hanging in the usual dependent position occasions great pain. We have under observation at present a case in which the long exposure to the X ray has produced these symptoms, other exciting causes being positively excluded. The face showed the same series of changes as the hands.—*Canadian Pract.*, September.

Woman's Inferior Sensitiveness to Pain.—Ottolenghi reports in the *Cbl. f. Nerv. u. Psych.*, No. 7, that he has been testing with Edelmann's faradimeter the sensitiveness to pain and the endurance of pain in 682 women. He finds that women are less sensitive to pain than men, and that this sensitiveness is less in early life, increases to the twenty-fourth year, and decreases after that. The higher classes are most sensitive, and degenerates the least. He found the latter very obtuse to the sensation of pain. Endurance of pain varies between much broader limits in women than in men, reaching a maximum far beyond the masculine limit, possibly due to great "suggestibility" of the female sex. "General sensibility" reaches the highest point in the nineteenth year. He concludes from his investigations that sensitiveness to pain stands in close relation to the "psyche," while "general sensibility" depends upon the peripheral nerves. He consider woman's comparative insensibility to pain as a sign of her inferiority to man, as the uncivilized and degenerates are the least sensitive. He also attempts to prove a connection between this characteristic and her longevity.—*Cbl. f. Phys.*, August 8.

Might be Entitled to Accident Insurance.—A physician was insured "against bodily injuries sustained through external, violent and accidental means." While he was in his carriage on the highway, he attempted to administer to himself in his leg, for extreme exhaustion, medicine with a hypodermic needle. His carriage suddenly started causing him to accidentally insert the needle deeply into his leg. This, he alleged and testified, produced blood poisoning and suppuration. The physician who attended him recognized it as a case of cellulitis, with which the morphia used had nothing whatever to do, and which resulted from the introduction of the needle, together with some condition of the skin or needle. Five judges of the appellate division of the supreme court of New York heard arguments on appeal from a judgment dismissing on the merits the complaint in an action against the company which issued the policy of accident insurance, with two of the five dissenting that judgment is reversed and a new trial ordered. The court holds, Bailey v. Interstate Casualty Company, decided July 7, 1896, that the question whether the injuries complained of were sustained through external, violent and accidental means, within the meaning of the policy should have been submitted to the jury. If, in the use of the needle, an agency that otherwise would not have been in force, and which was the efficient cause of the injuries, was accidentally set in motion, it says that it sees no good reason why it might not be found that the injuries were attributable to the accident as the sole and proximate cause. As to the contention that the diseased condition of the leg arose from the use of morphin, and therefore within one of the conditions of the policy that upon the evidence it also holds was a question of fact for the jury to determine.

Regents Control.—The supreme court of Michigan holds that the constitution of that State gives the control of the University of Michigan to the board of regents, and that the legislature has no control over the university or the board of regents. On this ground it holds unconstitutional Act No. 257, Laws 1895, wherein the legislature provided that the board of regents should establish a homeopathic medical college as a branch or department of the University at Detroit and should discontinue the homeopathic college now maintained at Ann Arbor as a branch of the university, and transfer the same to Detroit. In consequence, it denies a writ of mandamus, which was asked in Sterling v. Regents of the University of Michigan, decided July 28, 1896, to compel action on the part of the board in accordance with the legislative will. It also suggests that the *attorney general is the proper party to move* in such a case, and a private citizen does not possess the right, without permission of the court, to apply for this writ to compel a public board to perform an omitted duty.

The Use of Oxygen After Ether in Surgical Operations.—Dr. William A. Morrison, of East Boston, Mass., relates several cases in the *Boston Medical and Surgical Journal* in which inhalations of oxygen most effectually and rapidly remove the unpleasant after effects of ether. From these cases he concludes: 1. That some cases receive much more benefit from its use than others. 2. That in the most favorable cases astonishing results follow, the nausea is apparently relieved or prevented, consciousness is quickly recovered, the breath is entirely deprived of the odor of ether in a very short time, and the feeling of malaise, so frequently complained of, is absent. 3. That some cases are not benefited (or are positively harmed) by its use. In another case of his, a man with a gangrenous foot, convulsions appeared soon after inhaling the gas, and he was therefore obliged to discontinue its use. He is unable to state why the man did not tolerate it. 4. That the best method of administering oxygen after etherization is by the use of a soft rubber catheter gently introduced into the nares until the eye of the catheter is approximately opposite the opening in the trachea. It seems to him desirable that all cases in which oxygen has been used after etherization should be reported, so that the profession should be assisted in determining what cases are likely to be benefited by the inhalation, and in what cases its use is contraindicated. This was recommended by Professor Jackson when ether was first administered.

Liability for Harshness in Examination.—In the personal injury case of Goodhart v. Pennsylvania Railway Company, which was decided by the supreme court of Pennsylvania, July 15, 1896, it says that the evidence in regard to the examination made by a physician on behalf of the defendant was not directed to the extent of the plaintiff's injuries, but to the severity of the examination. Its evident object was to persuade the jury that the character of the examination and the conduct of the physician in question and his assistants was unnecessarily harsh and annoying, and was a proper subject to be considered in assessing the plaintiff's damages. But the supreme court holds otherwise. It says that it must be borne in mind that a claim was being made against the railroad company for damages based upon an alleged injury received in consequence of an accident on its line In order to determine intelligently the extent of its liability, it was important for the defendant company to know the nature of the injury, and the extent to which the plaintiff was affected by it This could only be known as the result of a medical examination made by competent and experienced physicians The physician above referred to and his assistants were selected as proper persons to make the examination, and advise the company of their estimate of the plaintiff's condition, and its consequent liability If, in the discharge of their professional duty to their employer, they went beyond what was reasonably necessary and employed methods and tests that were cruel, and such as the judgment of the medical profession does not approve, and thereby inflicted injury on the plaintiff, the supreme court holds that they were liable for their own trespass, whether committed with malice or through ignorance But rudeness and incivility in the manner in which the examination was conducted, if rudeness or incivility can be affirmed of anything that was said or done in that connection, the court insists could throw no light on the extent of the injury actually suffered by the plaintiff, and the evidence referred to should have been rejected Damages for a personal injury, it says, consist of three principal items 1 The expenses to which the injured person is subjected by reason of the injury complained of 2 The inconvenience and suffering naturally resulting from it 3 The loss of earning power, if any, whether temporary or permanent, consequent upon the character of the injury—each of which elements it further discusses

Specific Immunity Versus Transient Protection in Cholera and other Infection Processes —Dr Pfeiffer in a *Deutsche Medicinische Wochenschrift*, April 11, having been employed in an inquiry concerning the different kinds of immunity that can be effected in the laboratory, offers the following as a part of the results of his investigations upon the subject of immunity The cholera poison is contained in the body substance of the cholera vibrio, so that dead, as well as living cholera bacilli show marked toxic properties The cholera poison becomes capable of absorption by the disintegration of the cholera bacteria, analogous conditions have been established as regards typhoid fever, anthrax, chicken cholera, staphylococcus infection, and apparently influenza Animals may be rendered immune to toxic doses of living cholera spirilla, and typhoid bacilli by previous treatment with various substances of bacterial and non bacterial origin This protection is transient, and does not depend upon specific changes in the fluids of the body, and is designated as resistance, in contradistinction to specific immunity In the blood serum of human beings and animals that have been exposed to the action of the living or dead cholera spirilla or typhoid bacilli, there occur specific protective bodies, which are thus capable of rendering aid in differential diagnosis in cases in which ordinary methods have failed, and these substances may be made to accumulate in the blood in concentrated degree by properly conducted immunization In their relation to chemic and physical agencies, they bear a close analogy with the antitoxins, from which, however, they are differentiated by their action While the antitoxins occupy a specific relation to certain poisons, and are capable of destroying these in the animal body, the anti bodies of cholera and typhoid fever are incapable of thus acting upon the poison of typhoid bacilli and cholera spirilla Their activity consists in the destruction of the bacteria, but this property makes itself manifest, as a rule, only in the body, and is capable of demonstration outside the body only under special circumstances These anti bodies are also found, though in small quantities, in the normal blood of animals and human beings They are neither bacterial products deprived of virulence, nor combinations of these with components of the immunized organism, but they are probably entirely new substances resulting from the specific reaction of the body to a specific irritant The evidence points to the view that the anti bodies are specific ferments It is possible that the antitoxins also are specific enzymes As fermentative activity plays an important part in the production of natural immunity, it is possible to relate natural and acquired immunity, antitoxic and bactericidal functions to a common general principle This report as will be seen, fully sustains the position assumed by this JOURNAL in an editorial entitled the "Failure of the Antitoxins"

A Question of Implied Contract —The defense to an action brought to recover for medical services rendered the daughter of the party sued was that the plaintiff was not in active practice at the time such services were rendered, that plaintiff was closely related to the family of the defendant by consanguinity and affinity, and the families were upon the most intimate terms, that for thirty or forty years plaintiff and defendant extended hospitalities, courtesies and favors to each other in the way of kindnesses and substantial benefits, without charges or any kind of legal obligation from one to the other, and that a greater part of the time defendant made plaintiff's home a general stopping place for rest, recreation and refreshments, and it was at these times and on these occasions and under these circumstances that the plaintiff, as the defendant then thought and believed, acting as much or more in the capacity of a friend than as a physician, examined and prescribed for the family of the defendant when indisposed The evidence both showed that the services of the plaintiff were rendered as stated in his account and that the relations existing between the parties was as stated in the defendant's answer, and that their conduct and transactions with each other were the same as alleged On the trial the court gave a charge to the jury to the effect that, if the plaintiff's demand was just and due he would be entitled to recover, and, further, that if they did not believe such account was just and due, and was contrary to law and equity, then they should find for the defendant The plaintiff asked a special charge upon the question of implied contract, which the court refused to give Under the circumstances the court of civil appeals of Texas holds, Bonner, v Bradley, decided June 13, 1896, the trial judge failed to properly charge the jury, and reversed the judgment which was rendered in favor of the defendant It says that when services are performed at the request of a party, the law will imply a promise to pay the reasonable value thereof, unless such request be made and acceded to as a gratuitous favor, and that if, at the time the services were performed by the plaintiff, it was not the intention of the parties that charges should be made for such services, then the defendant would not be liable therefor

Twin Extra uterine Pregnancy, One Fully Developed Fetus of Fifteen Years' Retention —The *British Medical Journal* quotes Dr Folet, in *Annales de Gynécologie et d'Obstetrique*, regarding a case of the above nature The patient, a Flemish woman, aged 49 years, had an abdominal tumor, dull, uniformly hard, devoid of all tenderness, movable in its lower part and extending three inches above the umbilicus, which was diagnosed as a fibroma, partially calcified, and abdominal hysterectomy decided upon As soon as the abdomen was opened an edge of bone (one parietal overriding another) was felt through a moderately thick sac of supple tissue, and the diagnosis at once amended to one of extra uterine pregnancy The sac did not appear to contain any fluid, it was partially adherent to the abdominal wall, from which it had to be detached with caution, it had many adhesions to the intestines, which were easily separated by the fingers Only one ligature was required and the tumor was only retained by its base, when with a circular rent it burst, and five sixths of the sac came away with the contents, leaving a funnel formed by the remaining sixth attached by its outer surface to the pelvic organs In the interest of the patient no endeavor was made to determine the exact relation of the sac to its surroundings the edge of the funnel was fastened by eight silk sutures in the lower part of the abdominal wound a large drain wrapped in iodoform gauze inserted in the peritoneum and the remainder of the incision closed Recovery was perfect The temperature never rose above 37 5 degrees C and in six weeks the cavity of the cyst was obliterated and the healing complete The structure of the cyst seemed to show it to be a tubal one It contained two fetuses, one (female) 16 cm in length, with well formed nails, had lived to term it was not, properly speaking, a lithopedion the tissues, though dense, were supple and nowhere calcified, and on sections of thigh and arm the skin and muscles were recognized by the naked eye and microscope The other fetus had died about the third month the thorax and head were much compressed, but could be made out and the members were distinct The cords of both ended at the lower end of the sac in a single placenta, the degenerated tissue of which was represented by reddish brown matter like touchwood, and broke into flakes on the slightest traction Some days after the operation it was ascertained through an interpreter, that sixteen years previous the woman had become pregnant, having before that had four children at term She duly quickened but at nine or ten months had a false labor, blood and membranes came away and she had hemorrhage for six weeks As she ceased to feel the movements of the child and nothing further happened, she persuaded herself that she had been mistaken, and that she had not been pregnant, the more easily because her abdomen diminished a little in size and her catamenia returned and continued until she was 46 A doctor whom she consulted two or three years afterward, while giving no definite diagnosis, deprecated any treatment She was led to apply to Folet on account of repeated attacks of pain during the last year, probably due to the peritonitis which caused the intestinal adhesions

Medico Literary Notes —A book by E Bonavia, M D , has just been issued by the Longmans, on studies in the evolution of animals, taking into account the markings of animals as well as their coloration

Cruden labored nineteen years on his "Concordance to the Bible," and immediately after its publication was sent to an asylum He never entirely recovered from the mental disease induced by this gigantic undertaking

Dr Conan Doyle lately confessed to the London Authors' Club that he first began to write to get a little money to pay some bills For nearly ten years most of his manuscript came back to him by return of post His first profitable article was for a trade paper Dr Doyle says the choicest moment of his life was when Thackeray patted him, a boy of five, on the head and praised him His last book, called "Rodney Stone, ' has a good deal in it about the fistic science, which was in its prime about a century ago

Messrs Thacker, Spink & Co , Calcutta, publish a new edition of "The Indigenous Drugs of India," which has been produced by the Rai Bahadur, Dr Kanny Lall Dey, in association with Mr William Mair Fifty copies of the book have already been purchased by the government of India The work is dedicated with permission to the Pharmaceutical Society of Great Britain, of which Dr Dey is an honorary member, and extends to over 400 octavo pages It will be published in London within the current month

Among the various devices now being tried to relieve Guy s Hospital, London, of its financial difficulties, is that of raising a sufficient sum to permanently endow a bed in memory of the poet Keats, who served a short time there as a medical student

In Huxley's "Autobiography" he stands up for truth as greater than facts, and life than information He says, "Life seems terribly foreshortened as they look back, and the mountain they set themselves to climb in youth turns out to be a mere spur of immeasurably higher ranges, when, with failing breath, they reach the top But if I might speak of the objects I have had more or less definitely in view since I began the ascent of my hillock, they are briefly these To promote the increase of natural knowledge and to forward the application of scientific methods of investigation to all problems of life to the best of my ability, in the conviction, which has grown with my growth and strengthened with my strength, that there is no alleviation for the sufferings of mankind excepting veracity of thought and of action, and the resolute facing of the world as it is when the garment of make believe by which pious hands have hidden its uglier features is stripped off "

The Medical Chronicle is the title of the medical journal conducted by the faculty of the Owens College, Manchester This college will open its winter session on October 2, and Mr Jonathan Hutchinson has consented to deliver the introductory address, in the physiological theater of the new medical buildings

Mr C C Bell, in *Chemist and Druggist*, writes of the medieval names of drug plants He says many of the English names occur also in Lyte, Gerard, Parkinson and the other old herbalists, and a considerable number are still in use, but these are not now in every case applied to the same plants as formerly Gerard gives others of them in his list of obsolete names, but when these are deducted a good many still remain which had gone out of use before he wrote Among these are some of especial interest Donnhoof (spelt "donnhove") is one It is the same as coltsfoot, "donn" or "dun" being an old name for horse, whence comes "donkey" or little horse "Wowel" and "feldhove" are names given to the same plant "Cetewale," which the glossaries give as English for "zodoar" (zedoary, a species of tumeric), appears in Lyte and Gerard as "setwall" a name for valerian, Chaucer, in "The Millere's Tale," names it along with licorice Wermode in these glossaries means "wormwood" and is the correct form Skeat explains it as "waremood" (preserver of the mind), Mr Mowat, with greater apparent likelihood, says it is "ware moth" (preservative against moths) This certainly accords with the French *garde robe*, and with our old rhyme

> ' Where chamber is sweeped and wormwood is thrown
> No flea for his life dare abide to be known '

which, however, Mr Mowat does not quote Wilde kevn, again (which appears in the glossaries under vicus quercinus, and is evidently an echo of the French qui de Chene), is not in Gerard Other names calling for particular mention, some of which appear in Gerard and some not, are "groundswile" (ground swallower), an appropriate name for so prolific a weed as groundsel, "wymalve" (French guimauve), for mallow, "hepebrede" (hip bread, for dog rose, "horse heal," for elecampane marygold is called "yellebotel," or yellow bottle Shepherd's needle, which Gerard calls "ladies' combe," is glossed less flatteringly as "pouclesnedele," which, on the authority of a quotation in Halliwell, may be taken as equal to devil's needle, dandelion (dens leonis) is "doleronue ," hollyhock as St Cuthbertscole bryony as "wildnep, ' burdock has given to it the name filantropos, because its seeds stick to men's clothes duckmeat appears in a particularly interesting form as "cibus anatis ang enedechede" (a clerical error for "enedmete, "ened" being an old name for duck) Similarly "paddocstol" recalls the old name for frog or toad "Cold as paddocks though they be, Here I lift them up to Thee," says Herrick's child of her hands in her "Grace before meat ' "Aleon' are distinguished as of three kinds, cycotrium epiticum and caballinum Opium appears as "opium Thebaicum' (indicative of its geographic source), glossed "succus papaveris albi" and "opium miconis, succus papaveris nigri "

The entry immediately following this is a sad muddle, being "Opium quirrinacium, lesera, quilleya, succus iusquiami, idem" This is in "Alphita" In the "Sinonoma" "opium quirrinacium" is glossed "assfoetida idem," what "quilleya" is, it is impossible to say, "iusquiamus" is henbane This is only one instance of many hopelessly confused glosses White, black and red poppies appear under their respective Latin names, and of the second we are told that diacodion is made Nothing more is said of their use *Cowslip* appears under "paralisis herba" as "cousloppe," meaning cowdung, a not very poetical name, "endyve" is under lactuca The glosses on dracunculus are interesting as specimens of the fancifulness of our forefathers "Dracuncia, asclepias, viperina, pentaria, serpentilla, colubrina, basilica (basilisk), cocodrilla (cockatrice), idem gallice et anglice, dragaunce" ("in English, dragons," says Gerard, who gives an equally long, but different, set of synonyms from Epuleius Barbarus) "Mandragora" as described at length are of two kinds, male and female, no other name is given to it "Sene" (senna), again, has as yet no English form, and it is interesting to note that both these plants are mentioned by Shakespeare in the form here given "Zinziber" also appears only in this form, and rhubarb only as reubarbarum

Hospitals

New Post Hospital for Fortress Monroe, Va —The Government will build a new hospital to cost about $20,000 Plans for the hospital have been received, and the work will be let by contract after thirty days' advertisement

Pennsylvania Hospital Annual Report —The managers of the Pennsylvania Hospital have issued their annual report, showing that in the Pine Street Hospital the patients remaining in May, 1895, numbered 210 New patients received in the year to May, 1896, were 2,408, remaining at latter date, 186, beds occupied, 2,618 A large amount of work was done by the out patient department, the visits aggregating 16,197 In the department for the insane the figures for the year were Women, new cases, 88, discharged, 82, remaining, 233, men, new cases, 77, discharged, 91, remaining, 181, total treated, 587, remaining, 414

A Cottage Hospital at Proctor, Vt —A new hospital at Proctor, Vt, was formally opened on August 8 It is a modern building, a short distance from the center of the town, and arranged to accommodate ten patients The first story has an accident and operating room thoroughly equipped with modern surgical furnishings One of the wards is also on this floor The domestic and executive arrangements are all in the second story The hospital has been built and equipped by the Proctor Marble Company, and while primarily intended for such of the employes as may need its services, it is to be open to any person in the village The management has been placed in the hands of a committee of townspeople The district nursing in the town, which is already completely established, is now to be done from the hospital by its training school The attending physicians thus far appointed are Drs J M Hamilton of Proctor and H H Swift of Pittsford —*Boston Medical and Surgical Journal*

Philadelphia

Dr B Meade Bolton, Director of the Bacteriological Laboratory, wishes it to be distinctly understood that he is not responsible for the recent establishment of the plant in the City Hall for the manufacture of disinfectant solution, known commercially as electrozone The tests which have been alleged to have been made in the city laboratory he states were not made by him or under his direction and that he has not had anything to do with testing, reporting or publishing anything in regard to the matter, which is understood to be under the supervision of the City Board of Health or some of its officials

The report of the unsanitary condition of the League Island Navy Yard, arising from the fact that cases of typhoid fever have occurred recently in several vessels which had been fitted out at this place, has led to an investigation which is now in progress by the authorities at Washington The Board of Health has not been able to find any case of typhoid fever at the station or within several miles of it The water supply is not derived from the city pipes, but from cisterns filled with rain water so that the infection is not due to the use of water from the Schuylkill, and there is no great prevalence of typhoid in the city at present

THE PUBLIC SERVICES

Army Changes *Official List of changes in the stations and duties of officers serving in the Medical Department, U S Army from Sept 19 to Sept 25 1896*

A board of officers is appointed to meet at the Headquarters Department of the Missouri Chicago Ill on Monday Oct 5 1896, at 10 o'clock A M for the examination of such officers of the Medical Department as may be ordered before it to determine their fitness for promotion Detail for the Board

Lieutenant Colonel Albert Hartsuff Deputy Surgeon General
Major Henry Lippincott Surgeon
Captain Norton Strong Assistant Surgeon

The following named officers will report in person to the president of the examining board appointed to meet at Chicago, Ill, on Monday, Oct 5 1896 for examination for promotion

First Lieutenant Henry C Fisher Assistant Surgeon
First Lieutenant Henry A Shaw Assistant Surgeon
First Lieutenant Charles F Kieffer Assistant Surgeon

Major John V Lauderdale, Surgeon will upon the arrival of Major Egon A Koerper Surgeon at Fort Crook, Neb, repair to his home and await retirement

Major James P Kimball Surgeon is relieved from duty at Fort Wingate New Mexico and ordered to Fort Columbus N Y for duty, relieving Major John Van R Hoff, Surgeon Major Hoff, on being thus relieved is ordered to Vancouver Barracks, Washington for duty relieving Captain Rudolph G Ebert Assistant Surgeon Captain Ebert, on being thus relieved is ordered to Philadelphia Pa for duty as attending surgeon and examiner of recruits relieving Captain William W Gray Assistant Surgeon Captain Gray on being thus relieved is ordered to Fort Apache, Ariz, for duty relieving First Lieutenant Irving W Rand Assistant Surgeon Lieutenant Rand, on being thus relieved is ordered to Fort Clark, Texas for duty

Navy Changes *Changes in the Medical Corps of the U S Navy for the week ending Sept 26, 1896*

September 23 —*Passed Assistant Surgeon G A Lung, detached from the* Vermont and ordered to the naval hospital Chelsea, Mass

Passed Assistant Surgeon H D Wilson detached from the Chelsea, Mass, hospital and ordered to the 'Bache'

Passed Assistant Surgeon G H Barber ordered to the Naval Academy

Assistant Surgeon M K Johnson, detached from the Bache' and ordered to the New York'

Assistant Surgeon F C *Cook, ordered to the* "Vermont"

Change of Address

Butler T J from Chicago to Lockport Ill
Case C E from Tacoma to Everett Wash
Johnson C W, from 625 Locust St to 2309 Locust St St Louis Mo
Todd F Walton from Coronado to Camp Capitola Santa Cruz Cal
Taylor, P K from Kingston, R I, to 211 W 139th St, New York, N Y
Walsh, T C, from 330 Grove St to 860 Greenbush St Milwaukee Wis
Wiggin, F H, from Littlefield, Conn, to 55 W 35th St, New York N Y

LECTURE

MEDICAL EDUCATION

Opening lecture delivered at Rush Medical College, Chicago
September 29, 1896

BY EDWIN KLEBS, M D
PROFESSOR OF PATHOLOGY

Ladies and Gentlemen The wish expressed by my new colleagues that I open the lectures of this new year of medical instruction by some considerations of our work, laid upon me the somewhat difficult task of explaining my opinion, in a foreign language, on the organization of schools in this country, with which, also, I am not yet perfectly acquainted

You must not think that this will be a confession of my ignorance of American history and institutions On the contrary, I have always, from the time of my youth, inspired by the treatises of Ralph Waldo Emerson, loved this land At the time of the great civil war I eagerly studied the work done by your fathers, who, destitute of everything necessary to carry on a successful war, decided to live or die for liberty and humanity

I was astonished at this time to acknowledge the origin of a new war hygiene, later further developed in the great wars of the old country Comparing the great losses in the Crimean war, which preceded the American civil war, with those of the Franco-German war of 1870, you will not fail to see the great progress in this new field, principally, as I think, effected by the distribution of the wounded and sick over vast areas, by means of the mighty streams

It seems to me that the American people, impelled by urgent necessity, became more and more inventive, and learned more in a few years than it would have learned in centuries without that impulse

The wonderful development in this land that you all know, from your own experience, now followed during the short period of twenty to thirty years All facilities were enhanced by the confidence in the restored Union, enormous wealth and prosperity, such as were never known before in history, were arising from the soil of the new land

Naturally, then came depression In the restless strife for improvement many things, without which a people can not be happy, were not taken into account I only mention the devastation of woods, threatening a change of clime, unless replanted systematically, an injury not otherwise to be remedied

Political and financial influences have more and more increased the internal difficulties, so that now will come a time when the labor of the whole land will be required to sustain this prosperity

But how will the people endure this change of conditions, the irreparable loss of so many facilities? I think that they will accept the new position, the harder strife for life, the conditions of life impaired and narrowed also by the competition of the whole world This confidence is based in the first place, on historical facts A people who have surmounted the hardships of a civil war will find a method also in this harder time, but in another way

Not the pioneer and the digger, but the teacher and educator will be the leaders in the new course Science will be the aim and purpose

The educational question now moves the whole world European civilization based wholly on the old classic traditions of Rome and Greece, has reached, especially in Germany, a standard in classic education which seems to be incompatible with the claims of modern life Natural science will more and more supplant the ancient literature and the modern philologist finds that the modern languages have attained a higher certainty and clearness by which to express the modern thoughts than the dead languages now occupying nearly the whole time of the scholar

The reform of higher school education now commencing in Germany, will save our country from imitating the so-called classic studies Let us fill the mind of the child and the youth with a broad knowledge of earth and heaven of living beings and dead material, of human life and thought, history and philosophy, so that they may understand the coming life and be able to distinguish the good and the evil, the just and the unjust, religion and morals must have a prominent part in this system of education What I wish to say is this, that for the young man or woman willing to devote themselves to medical science, a nonclassic education is quite sufficient But the requirements of preliminary education necessary for admission to our colleges, seem to be totally insufficient Unless certain literary colleges have been attended, an examination in writing, in the branches of a good English education, including algebra as far as equations of the second degree, the first book of geometry, English composition, elementary physics and the elements of the Latin language should be substituted, chemistry and physics will be taught in the freshman year

I do not find in the program the descriptive natural sciences, the natural history of plants and animals, the geology and mineralogy, which contain the elements of so many parts of the medical science, not to speak of knowledge of human history, art and thought I am quite sure that a great number of our pupils have completed their education in these directions, but I doubt if that is the case with everyone

I do not pretend to propose reformations, but I do hope to find the young men better educated than the scanty requirements for admission to the leading medical colleges lead me to believe

For comparison, I will give a short outline of the requirements in German universities, in natural history only The young men entering the university have learned a great deal of natural history at the gymnasiums, but before commencing the medical studies they must spend a whole year's course in natural sciences, such as botany, zoology, chemistry and physics, including practical work in microscopy and the chemic laboratory.

If we look at the schedule of Rush Medical College we will perceive that in the freshman year no more than 745 hours are devoted to study, in the following three years from 870 to 1,036. I think that one could very well dedicate 150 to 200 hours to the study of botany and zoology in the first year. But this, as other practical questions, must be considered at another time. Furthermore, I would wish for a certain knowledge of the German and French languages, already required by the Johns Hopkins University, also some ability in drawing. Without knowledge of these modern languages the medical student can only make use of the English literature and translations from the German and French, but as the greatest part of medical literature and the most valuable is published in periodicals, the student can not fully understand the medical literature of his time without this knowledge of modern languages. As the development of science is a very rapid one, scientific work is not possible without personal literary study.

But we have given enough detail on medical teaching. Let us now look at the American students and their qualifications for this science. As I have had many opportunities to teach Americans in European laboratories, I am prepared to speak upon that point with due reservation. First I will say something about the ladies studying medicine abroad. The greatest number I had in Zurich were Russian or other Slavs, German, Swiss and American. The best prepared for study were Swiss, American and German. In diligence they surpassed nearly every male student and as far as memory is concerned, it was very difficult for our male students to attain better marks than the female in the examinations. In the anatomic and microscopic work, over which I made personal observations, I found American ladies among my best workers, in the composition of publications there were some differences, however, depending more upon the personal character than upon mental faculties. One lady whom I highly esteemed for her assiduity and very clever work, labored somewhat under a too much developed pride, declining every help in the composition of her paper, which, based upon delicate microscopic researches, would have made more impression if the points and the deductions had been more thoroughly discussed. I do not know if that was a personal propriety, but I can understand that a woman prides herself on independent work, this pride can be a very good support in the hard work awaiting the doctress. I shall ever remember another American whom I had the pleasure to aid in her original work, as the best example of a medical student, fitted to do any scientific work. In this direction I must give the American ladies the first place and I hope to see here the same attainment in practical medicine.

As to the qualification of American men for scientific medical work, there can be no doubt. From my youth to the present time I have had many opportunities to come in contact with them as a teacher, and can openly express my opinion, that they would not, in any way, remain behind any other people, only being handicapped by their preliminary education and imperfect knowledge of foreign languages. But these slight defects were compensated for by a burning zeal for learning. My first experience dates back to the early sixties, when I was assistant of Professor Virchow. My first pupil, a man as old as I, was a Californian and showed, perhaps, more enthusiasm than your Eastern people, but I will never forget his open-hearted joy, when he understood a difficult matter, explained by the inexperienced teacher, in pretty bad English. And I have made the same observation, repeatedly, through a quarter of a century. All young Americans that came to me for study, were brave, joyful, enthusiastic people, but sometimes a little deficient in school education. They have all been my friends.

You, probably, all know the cause of these characteristics. The American life is a practical one, and the arts and sciences, here, come in second place. But I am sure this state of things will change before long. Deficiency in education is more and more improved and there are many men of the highest and most refined education in liberal arts and sciences. One of my friends in Germany, a learned man of high standing, a deep critic of Göthe, stated that he was astonished by American visitors, oftentimes finding that they had the most profound understanding of German literature and philosophy. That is a good indication of what can be done by your people in medical science also.

In medical practice we can certainly meet any competition, but not in medical science. The reason for this is to be found in the organization of our medical schools, which I have already touched upon. I understand very well that these organizations resulted from compromises and that under given circumstances, for the moment, higher attainments could not be demanded without driving a large number of students into the hands of so-called medical colleges, which one of my friends designated as "paper mills," a shameless scattering of diplomas for money.

Regarding these facts I can not find a better remedy than to place the higher education in the hands of the Federal Government. This would present many difficulties, as I know from my experience in Switzerland, and I would not like to interfere in practical questions. But we can take these matters out of the hands of the government and regulate them. By "we" I mean all good citizens who find that the prosperity of the country depends upon the education of the people. Very much is done in this direction. For our prominent scientific institutions are founded by private individuals, by donations, often rich men restoring a part of their earnings to the people, the well-conducted work of whom has procured these means. A political economist in Germany has named that the "inheritance of the people." "To give is more blessed than to receive," said Jesus, the greatest socialist. Yes, we will bless these rich men who will help in the education of the people and perhaps prevent the day of wrath. But not alone to the rich people should the appeal be made to assist in the educational question. Every physician, every patient is interested in this work and can afford to promote the higher medical education. I am sure the generous American people will favor progress in higher scientific education.

Here arises a very important question. Is the efficiency of such institutions for higher learning assured by money alone? Can money buy such institutions, as it can buy railroads or steamships?

The success in original scientific work depends more upon the worker than upon the external conditions of work. In my youth I have seen Helmholtz, the great physicist, work out his great discoveries in optics with the simplest means, and calculating with a child on his lap. The great mathematician, Gauss, when asked how he had found his new methods enormously enlarging mathematic conception, replied "By repeated thought over the same matter." So we see that the personal conditions for scientific work are given everywhere, if there is a quiet place for thinking and men apt for this work. An exceptional mental faculty is not necessary for this, as not every learned man needs to be a genius. Continuous work is sufficient if the right way is laid open. Such indicators (Wegweiser) guiding the seekers after knowledge will arise in every country where learning is esteemed and supported.

I have experienced a striking example in my own life. I came to a university, in a land where science was not much developed, but proud of its great political power in a past time. This aristocratic people, with high self-consciousness, resented bitterly that so many strangers were called by an intelligent government to fill the chairs at the university. Some wished to injure the intruders, not personally, but by diminishing the number for instruction. A politician of high standing was induced to promote the attack, which would be adverse to the development of the university, when one of the professors opened the eyes of this political leader, showing the true aim of his associates, by saying: "You, as a liberal and reformer can not support an action against natural development. Give good seed to the soil and you will see good fruit ripen. Learned men can not be found everywhere. Take what you have and you will see, that in some generation, you will have enough support from your own countrymen." Thereupon the good man ceased to support his tempters and the chairs of the university are now, after nearly thirty years, occupied by a great number of native teachers, universally acknowledged to be of the highest rank.

What I wish to show by this experience is that higher study needs a thorough cultivation, continued for a long time. It is the same as with the cultivation of plants. If King Probus had not planted the grapes on the borders of the Rhine, the Rhine wine would not have won its world-wide celebrity. I tasted the California wines some forty years ago and I was not pleased with it, but now it is quite a different thing.

As we can not reform the whole system of higher education at once, we must commence slowly, warming and protecting the delicate plant sown in a soil in which, as yet, other plants, industry, farming, business of all kinds have grown so luxuriantly. If the soil commences to be exhausted by the one fruit, the good farmer will plant another. Science is a plant that has borne very good fruit in old Europe, why should it not develop here, when a young, fresh people, free from many prejudices of the old world, will strive to win the first rank in the great problems of the human mind?

But how shall we promote strong scientific work in our department, the medical science? In the first place you must change your opinion on the tendencies of the college or university. It does not suffice to have excellent instructors and well educated pupils, but we must have the will to give or receive more than medical instruction, sufficient for medical practice, or only for the examination. That would be the office of a high school or a university, in the sense of German universities. More than in other countries, you will find that these institutions are founded not only for education, but also for observation.

The difference between a school and a university is not always comprehended as it should be here, nor in Europe. As a young professor, I often spoke with business men about the difficult task of a university professor, but they did not understand me. "Oh," one said, "I think, in the first year, that it may be very difficult to lecture so much, but later one learns that." This is only too true, many professors learn to repeat the same lectures, and very amusing anecdotes are told in Germany about teachers accustomed to do this. One of these learned professors, reading his lecture absent-mindedly, also read the foot-note: "Here I like to make a joke." But I can assure you that this sort of professors died out, and from that time the acknowledged glory of German and other universities commenced to fill the world and attract people from every country. By these remarks I do not mean to say that German universities are perfect. As the devil always sows weeds among the wheat, so there the high position of professorship has attracted many inferior people who rely more upon protection than personal worth, and the egotism of many professors goes a little too far. Where there is much light there will also be shadow, but at all events we can look to German universities as the best examples of our scientific schools.

The first object of these schools is, and must be to educate the pupils to scientific and practical work. We must educate them to be independent observers, for a physician must have this quality, and without it he will not enjoy his task. He may fill his position very well, operate and prescribe, but if he does not look at his patient with the eyes of an observer he will fail to see many features of the highest importance. To the superficial physician not trained to careful observation, one case looks like another and he will be astonished if the expected effect of a certain remedy does not appear. It is, as with a savage people or a flock of cattle to the unexercised eye, they seem to be all alike, the observer, however, if he be an experienced traveler or a cattle grower, will see the differences. Certainly the good physician will learn, in the office and at the bedside, what he has not learned at school, but it would be better if he would go out into the world wholly instructed and experienced. Scientific work, done while a student, will aid the practitioner.

Hoping that you are convinced of the great importance of this truly dominant question, I will add some suggestions as to what should be done in this direction. First, every laboratory should be so arranged that a certain number of students and also of younger graduates could work, not in learning the elements, those must be understood, but for original scientific work. The smallest problem which we attempt to solve brings with it more elucidation than the reading and memorizing of a whole text-book. I fear that in our method of teaching learning, memory is too much relied upon, recitations prevail and not discussions. With young people, working on problems there must be more discussion than recitation. I prefer a student who does not know so many facts, numbers or figures, but who understands the connection of facts and how to make conclusions from the known to the unknown

In the laboratory opened for the work of students, it is not necessary to give long lectures but to discuss the matters in a conversational manner

Whoever is farther advanced in his work, will come and expound his results to the teacher and his colleagues From the discussion new thoughts will arise not before given by the teacher The scholars can learn without feeling that they are being instructed I hear that such a system has been commenced here in private primary schools, if it is practicable with children, why should it not be with thinking men?

But in this matter another side is to be taken into consideration If we have such laboratories who will work in them? The student is busy the whole day and the young physician must oftentimes attend to making his living I do not think that people are poorer here than in Germany, where all this is done, but if so, the means for such work must be found and I do not doubt but it will be In German universities we have so-called stipendia, which enable the poorer student to continue his studies, and beside that, we do not want to have medical proletarians (a very good word of Billroth) Whoever undertakes this noble study should first find the necessary means The poor should not be excluded, but they must show the true qualifications

For the young graduates, working to perfect their education, I would recommend the two appointments which, in my opinion, have made German universities great, first, the doctorate, obtained by scientific work, second, the private university teachers (Privat-Docenten)

The title of doctor, historically, means more than that of physician, it expresses a scientific qualification, shown by original scientific work For that degree the publication of a dissertation is required, that is, a scientific treatise and theses, scientific questions which the applicant will defend in free debate against every one

This venerable practice has been, as all human things, liable to deterioration, but it has influenced, in a very ostensible manner, the high standing of the profession Innumerable students of medicine have been compelled, by this custom, to do original work, or treat clinic observations in a historic and critical way Certainly the dissertations have awakened many literary talents which would have slumbered without this incitement

Graduation or examination is necessary for the *Doctorat*, the latter is intended to show the qualification for scientific work and teaching It is therefore indispensable for every physician teaching in a medical faculty

The private lecturer, privat-docent, is a position quite unknown in English and American colleges, in France the professeur agrégé occupies nearly the same position The title privat-docent is conferred by the faculty, on application, for a certain branch of science He lectures in the same manner as the professors, mostly supplying gaps in the regular lectures or giving lectures on special parts of the science, elaborated by his own work Many of the private lecturers are assistants, and are given the opportunity by their chief to deliver special courses Without going into particulars, one will see that this institution is highly adapted to the education of professors

I wish to submit this institution of private lectures to the earnest consideration of leading men in this country Having so far only touched upon the student epoch of medical men, we can not make the whole importance of this discussion quite clear if we do not explain the standing of our profession and science in public and private life

The profound change which our science has undergone in the last century will be made clear by some historic references In the earliest times medicine was in the hands of the priests and based only upon occasional observations such as were made by the people Hippocrates destroyed the secret and put these ideas into systematic order The observation of facts became controlled and the work of physicians subjected to general rules, governed always by moral laws, highly appreciated at all times by the true physician Since that time the work of the physician possesses a sacred feature The patient needs to rely, with full confidence, on the knowledge and the truthfulness of his physician He must know that he can not be deceived, although errors can not be entirely excluded If the physician has any doubts consultation may be sought

The medical profession must be so organized that it will be the best for the public Quackery and evil conduct are more contemptible than in any other occupation Where the government does not protect the medical profession it must protect itself, as is done here by the code of ethics, accepted by the AMERICAN MEDICAL ASSOCIATION

This organization, securing the interests of the public as well as of the physicians, has sometimes roused distrust rather than confidence, but a thinking man will congratulate himself for having a medical profession caring for its honor This position of the profession seems to be one of the principal features which attracts the young men to our lecture rooms The practice is not so lucrative as in the old times, when one would say "*dat Galenus opes*" The sense of humanity forms another attraction to the medical science, if the physician can help, he is loved as a god, and to the incurable he can always bring comfort and diminish their suffering

In our time, in which the strife for gain seems to reign, the people have double interest that our profession preserve these feelings, and I hope that the public will support them It will be to the interest of the patient that he follows obediently the prescriptions of his physician I have seen so many patients ruined by their feeble, distrustful character, changing from one physician to another, thus losing the best time in which they could have been saved But, on the whole, I have found the American to be an excellent patient, not excited, not nervous, but quietly doing and sustaining whatever was necessary I have never elsewhere seen so much courage in enduring pain

But the position of the physician in our time must be looked upon from another side The change in the medical principles, effected in the last thirty years, is so enormous that weaker minds could not follow On the whole, one can say that the younger generation has fully adopted the new theory of the bacterial causes of disease, though not always willing to make the necessary deductions

How great this change was may be shown by an example The two pathologic conditions, which alone nearly governed the old pathology, were "fever" and "inflammation" The seething of bad humors or juices in humoral pathology, the struggle of the soul, the Archaus of Stahl, through many centuries formed personifications of disease, very apt to be attacked by the zealous physician, who mistook the signs or symptoms of the disease for the disease itself Under this delusion such things as "essential fever," or fever in itself were spoken of Later, under the auspices of a more developed physiology, one tried to explain these phenomena by the doctrine of irritation Albrecht von Haller has shown that irritability is the general property of all living substance, a property consisting in the outbreak of the genuine activity of the organ, after an external influence has acted as an irritant So the muscle will contract, if it is acted upon by mechanical, electric or chemic influences in the same manner as it does when irritated by its nerves through the action of the brain or by an electric current The action producing the irritation can be of very different nature, the effect produced upon the body is always the same You will understand this if you think of the works of a clock moving in the same manner, whether its spring or pendulum be put in action by the hand, by an earthquake, or by removing a hindrance

This theory seems to best explain the two symptoms governing, or of disease itself From Broussais to Virchow this explanation prevailed, giving very good indications for therapeutics If the irritability of an organ or the whole body is increased, one has recourse to remedies of a soothing, mitigating action, if the irritability is deficient, one must irritate, if the two processes do not help, according to the doctrine there only remained the counter-irritation (contrastimulus) If, for example, an inflammation of a knee-joint was treated without good result first with cold later with warm poultices, there remained only a counter-irritant, the burning The consequence was that old country women, shepherds, etc , sometimes had greater success than learned physicians

This inadequate doctrine was destroyed by pathologic anatomy, which, from the end of the last century, was more and more developed in Europe, first in France and England then in Germany After many great predecessors, Rudolph Virchow developed a new doctrine which seemed, at first, to cover every logical desire, namely, the cellular pathology

This doctrine showed the composition of the body to consist of a great many living organisms, the so-called cells, bound together by the common action of vessels and nerves This theory disclosed manifold processes in disease, in their minutest details, it enriched our knowledge, but it did not advance our therapeutics, to the action of cells was confined the regulation of irritation So the cellular pathology was thought to have found in the action of the cells, the whole essence of disease, and the question, Why do the cells act in an abnormal manner? was asked no more

For Virchow and for many of his pupils and followers, the question of cause did not exist He declined to go farther, with the oracular answer of a sovereign, "We can not know all things"

I admire R Virchow very much, having been for a long time his pupil and assistant, having learned from him the finer distinctions of pathologic processes I acknowledge that he has enriched pathology more than any one else before him, but he did not have the right to command a stop to all other progress in our science The word "why" must always be used, if the knowledge does not cover the whole truth and does not explain the cause of action

Already a new dawn announced the bright day of our present knowledge Medical historians and geographers remembering the spread of the great plagues, and enlightened thinkers, as Henle, had, contemporaneously with Virchow's cellular pathology, proclaimed the theory of the external origin of contagious diseases, from living matter, the germ theory hinted at in oldest popular medicine The microcosmos were opposed by the macrocosmos in pathology

In our time the investigations in this direction had commenced, first without regard to pathology Pasteur had detected the origin of fermentation due to microbes, destroying the physical contact-theory of Justus von Liebig But Pasteur declared, fearing to oppose the dominating school of pathology, that these discoveries had nothing to do with pathology When later, in the seventies, he transferred the germ theory to pathologic questions, he had to suffer many persecutions, as I know from his own mouth

Already, many years before Pasteur recognized his error, the parasite of anthrax was found by two German observers (Pollender and Brauell), but were, by all leading men, declared as inorganized, or if bacterial nature was conceded, as consequent to the disease or organisms developed in the dying animal

A sort of madness seemed to have controlled the defenders of the old doctrine, so that even the excellent experiments of Davaine did not change the minds of stubborn *doctrinaires* Davaine isolated these organisms and showed that a single one was sufficient to infect and kill an animal The development being first local, at the place of implantation, and the general infection could be prevented by destroying or extirpating the infected part

Lister developed the same idea, the external infection in wounds, and commenced a reform in surgery, which was more and more refined and perfected later

At the same time I demonstrated the propagation of certain bacteria in the internal organs of the body after they had found entrance through natural openings or through wounds The abundant material of the Franco-German war of 1870 gave me the opportunity to show that these organisms, while spreading in the organs, always precede the cellular derangements Cultures and infection of animals in these and other cases of infectious diseases showed the causal nature of, probably, all contagious diseases By separating the bacteria from fluids, in the cultures, by filtration, we could demonstrate that only the bacteria produced the disease It was shown by Tiegel, my assistant, and later in Tokio, that the fluid had only toxic influences (1871 to 1873)

I also was very vigorously attacked from all points, especially from the medical side, whereas other learned people, such as Tyndall, were convinced of the importance of the new development in pathology Certainly many imperfections, unavoidable in a new research, may have given some reason for criticism The later researches of Robert Koch and others decided the battle on the fundamental principle in pathology This can be pronounced in the following thesis *Disease is the struggle of two organisms the one invading the other*

If I have explained my opinion clearly enough you will see what can be done for scientific medical education By my lectures, which I will give in this college, I will attempt to inspire the student to do original work, which is the only way to promote the scientific standard

A MEDICAL ASPECT OF CRIME

Read in the Section on Neurology and Medical Jurisprudence at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga May 5-8, 1896

BY A C CORR, M D
CARLINVILLE ILL

Aside from the uncivilized barbarism that would induce a barbarous or half civilized person to commit outrages on the individuals of a neighboring tribe or state while practicing obedience to his own tribal laws, there are exceptions in which the individual is not true to his own tribal or state laws These he continually violates, through some unknown impelling force that makes him act in utter disregard of the good, safety and comfort of all This latter violation is usually called crime

Now in all the mutations of the silent revolution that has wrought so wonderfully since the debut of an organized Christian civilization, we have room for so many different phases of a variation of progress that we have amid a high Christian civilization, great irregularities in which individuals are untrue to their assumed, acquired and inherited responsibilities and obligations, and tend frequently or constantly to violate those laws, written and unwritten, which are for the good of all, both living and unborn Besides this variation as between civilization and barbarism as to the highest types of that which we may call tragic crimes as between nations, there is quite as much variation or want of consistency in our civilized Christian and free country between communities and states What is a crime in one state or city is not necessarily such in another What is a crime in one section is not in another, and some things that are a violation of law on one day in the year or week is not on another Amid this almost inconceivable and inscrutable maze of varying conditions, individual and collective, local and general, we are called on in this ASSOCIATION, established for the well-being of society, to discuss the Medical Aspect of Crime

As far as the discussion in this paper is concerned it shall be based on the fact, that the brain and the nervous system are the physiologic organ of the mind and intellectuality, and that every grouping of ideational activity, or well defined mental faculty has its origin in the functional activity of brain or nerve cells and fibers, either local as in areas, or disseminated throughout the nervous system, or both local and disseminated, and that *morality*, the ethical sense, the sense of moral uprightness, of justice, of right between men, people and things, has such an origin, that it is a faculty of the mind just the same as the will of the reason, and that as such it is subject to the same laws as the functional activities of other organs that it is susceptible of being cultivated, of being repressed, of becoming increased by education and activity, of being diminished by neglect and occupation, of being perverted as in diseased conditions manifested in a class of criminals, that it is deficient in many persons to a greater or less degree In other words there are children, youth, adults and mature persons who are moral imbeciles from congenital deficiency of the moral sense.

This faculty of moral sense or morality is the inhibitory faculty of the mind, the let or hindrance to the human expressions, activity and conduct, modified by the will, the reason, the judgment, the understanding and the impulses and intellectual delusions

This faculty of morality is the latest and best results of man's long continued culture and its exercise is the highest function of his very complicated cerebral and nervous mechanism

With this physiologic source and condition of crime before us its treatment is greatly simplified When amid the mutations in progress of development from barbarism to civilization and advanced christianization, influenced by atavism and connation the impulse to commit an act is felt that belongs to the criminal calendar, that is, to do that which is in disregard of the rights of others and is hurtful to the well-being of the civil social compact, and is in violation of law written or unwritten, the individual sense of justice and moral uprightness intervenes and inhibits or sanctions the act, just in proportion to the development of the moral faculty of the individual

Now, would you have crime lessened? Then you should cultivate and develop the moral sense and repress the emotions I can not give here a tithe of all the details this cultivation would embrace, but certain it is that some code approximately correct should be formulated and put in practice expressly for this purpose Something that would teach children as definitely to exercise the moral and ethical faculties as there is to teach the exercise and development of the reasoning and intellectual or mathematical Children should be taught as early as possible *that there is a principle of right and justice in the abstract*, irrespective of any mere religious sentiment or superstition Each child ought to be impressed, if in no other way, by mere precept in a round of words, that he who has not an average moral perception is a moral idiot and is to be held in apprehension as one unsafe to trust Lessons in morals ought to be formulated and a spirit of emulation engendered that would cause them to strive with each other to learn the most of them These lessons should be elementary and advanced and graded in adaptation to the ability of each child to grasp and comprehend them *And every school of whatever character*, should be required to rigidly teach them, *for the exercise of morality, to the extent of being just and upright in conduct and character, is the best and highest function of the human brain* In this course each crime should be designated and its heinousness expatiated on and a thorough understanding of its turpitude required, and that its commission and practice would lead to still further immoral practices in the individual, propagate the same or similar practices by inheritance to others *And over all this ought to be held* the *terror* of *lawful punishment* For he who can not or will not learn, let him be deterred by fear of pain and penalty and let the seal of disapprobation be placed on every act that violates the least of the moral code

This much should be done for the individual from childhood up, and should not be neglected, and whatever religious influence that may be deemed proper should be added If anyone can be deterred from criminal or immoral practices through fear of impaired *future* happiness, by all means give him enough to answer the purpose It is the practicing that cultivates more than the mere tendency inactive

At present the public schools in our country, through which most of this grade of work in moral culture must be done, is incompetent for the task There is among school teachers as well as among the laity in general no definite idea as to the difference between morality and religion, between moral uprightness and the mere ritualistic processes of a beatific worship

I once had occasion to investigate this subject among public school teachers in my own State, and I dare say they average with those in other States Some said morals is a theological question, and if we attempted to teach it in schools it would give rise to religious sectarian wranglings that would impair the harmony and usefulness of the school, and if this or that teacher inculcated his or her moral ideas (religious views) it would create dissension and independence among the patrons of the school because of their varied religious beliefs One who was in high esteem as principal of public schools said in substance "that the question of how to promote the morals of my pupils has given me a great deal of anxiety and is a matter I never felt satisfied how to manage, owing to the varied religious views entertained by my teachers and pupils I have in one school a class of six or seven studying natural sciences, two members of which are believers in the theory of evolution, and it gives me a great deal of annoyance and anxiety for fear they will ruin the morals of the remainder of the class and in fact infect the whole school" Other teachers replied to my queries that they would leave the question of morals or religion to the Sabbath schools, the churches, the sectarian schools and the colleges There were still others who frankly admitted that the question of teaching morals was not well understood and criminally neglected

Now, I do not think I misrepresent the great body of divines and religious instructors, including all denominations from pope, priest, bishop, theologic professor and clergyman to pastor, when I say that they are not more systematic and definite in their conception of in what moral uprightness consists and how crime is to be prevented

Nor has the legal profession elucidated and proposed a better plan than the hurling of statutes and sentences of punishment Now, what shall I say of the medical profession? Have we elucidated any better or well devised method of defining morals and cultivating the moral sense? In fact I doubt not that when this point is discussed that it will reveal quite as wide a range of different ideas as to the moral sense and faculty of the brain and mind as the classes to which I have referred

But having to do with the brain as an anatomic organ and its physiologic phenomena, the mind in the abstract, it is our incumbent duty to determine whence the source of criminality in the individual as far as his mental composition is concerned and what additional plans shall be formulated for its prevention The conclusions arrived at on this point shall constitute a basis for the consideration of the medical aspect of crime

The moral defect with its criminal tendencies is always congenital, many times hereditary and always modified in a greater or less degree by *environment* and *synergistic influences*

By *congenital* I mean the inborn tendency, which mental condition is a derivative complex, much like a double decomposition in chemistry, and by which a mental composition is transmitted congenitally that is unlike either parent in moral perception, yet like one or the other, or both in many other respects This is *congenital* moral imbecility, while an *hereditary* moral imbecility must be like one or the other or both parents

The congenital variety of mental complex is that in which criminal children are born of amiable parents, or amiable children of criminal parents Many instances of both varieties I have observed

Having established in a fairly plausible way that the tendency to crime is inborn and consists in a defective mental composition in which the moral perceptions are weak or deficient and that it may be cultivated like any other mental faculty, it may be well to consider some one or two conditions of environment or synergistic influences that coöperate with a slight or marked criminal tendency to make the criminal To a large extent all men are creatures of association or environment Many with only slight tendencies are schooled out of or away from crime While many are schooled into it who but for such synergistic influences would have always remained guiltless

Beyond these suggestions I would be recreant to my trust were I not to arraign the liquor traffic as being the greatest despoiler of human morals and well being While we do in our associated capacity much to school children and youths out of and away from crime, yet we tolerate and perpetuate a traffic that unschools and dissipates much that our well designed efforts have wrought The use of alcoholic beverages is always to degrade and debase the moral sense in the individual and disorganize society It never elevates or cultivates a moral sense, but degrades and tends to make criminals just in proportion as it is used It never sent a child to Sabbath school but has sent many to the penitentiary and the gallows If a man uses a thousand barrels of it, it does not do him as much good, based on his necessities, as the eating of a teaspoonful of meal

Its tendency to produce crime and make criminals can be proven by the history of any county in the United States where the sale and use of it has been prohibited for only one year, for just in proportion to the efficiency of the restricted sale and use of the beverage among the citizens will crime and criminality have been diminished

I do not think that the destruction of the liquor traffic would by any means prove a panacea for all crime, but its synergistic influence amid a degree of moral imbecility is at the present time greater than all other influences combined

Some eminent medical gentlemen have argued that some one or more organic instincts are responsible for most all the crime, and that a surgical procedure or operation would prevent crime and reform the criminals The most remarkable contribution to the discussion of this character that I have seen is a paper by Dr Robert Boal to the Illinois State Medical Association in 1894, entitled "Emasculation and Ovariotomy as a Penalty for Crime and the Reformation of Criminals"

The discussion was made under nine considerations which were practically these

1 "We are taught by both physiology and psychology that all human beings are controlled in their conduct and actions and appetencies are expressed

through their organic instincts Of these two are of paramount importance They are love of life and sexual love The first is the strongest and outlasts all others Next is love of sex, which dominates human conduct and desires Its bestowal was wise, but when uncontrolled it is potent for evil "

2 "The greater proportion of the crimes characteristic of the criminal and vicious classes may be traced directly and indirectly to the influence of this uncontrollable and dominating sexual love The rapes, homicides, suicides, defalcations and embezzlements may be ascribed either directly to sexual love, or to influences associated with it So well is this understood that when we hear of the cashier of a bank absconding with its funds, or a trusted clerk robbing his employer and betraying his confidence, almost the first comment heard is, 'Oh, there is a woman in the case' With scarce *an exception*, there are few vices in the calendar of crime, licentiousness, prostitution, intemperance, gambling and others that are nameless, that are not designated, associated with and maintained by sexual love "

3 "The physical or structural characteristics of the criminal and defective classes are produced, reproduced and multiplied, and perpetuated by intermarriage or sexual commerce of persons of like defects, and we have accordingly the results of living activities of matter or what is called heredity "

4 "By the imposition of the penalty of emasculation and ovariotomy we destroy the capabilities of these defective criminal classes, to inflict injury upon society, thus depriving them of the power of reproduction "

5 "For the purpose of intimidating others from the commission of crime, while neither cruel nor vindictive it is more terrifying and repulsive, next to death, than any or all modes of punishment The loss of sexuality as a mark of manhood is so utterly abhorrent to all men that it would be avoided if possible by all individuals *not hopelessly insane* "

6 Practically, "By unsexing all constitutionally depraved convicts we would curtail such production and aid nature in natural selection and the survival of the fittest "

Seventh and eighth considerations are conclusions based on the acceptance of the six preceding referring to the results and effects of emasculation and ovariotomy on the disposition of the individual, and that as a punishment would not excite revenge, etc

Ninth consideration is a general *statement* as to range of application of the punishment, to the effect that it might be safely applied to insane persons, cranks and paranoiacs

To this ninth consideration I have only to ask, Would emasculation and ovariotomy change the delusions of the insane and make them safe citizens at large in society? I have quoted these 'Considerations" because they embody an idea that is held by many both in the medical and legal professions I think the idea is untenable as a whole I discussed them in a paper before the same society a year later, when I replied to the "Considerations" seriatim In the discussion of this paper Dr N S Davis of Chicago, said, "I have seen nothing in my observations in human society to make me believe that human depravity is greatly ruled by simply the sexual *organs* in either sex That they are capable of exerting a predominating *influence* in individual cases, as much and probably a great deal more owing to bad training, bad education, bad surroundings than to any inherent vice in these organs, is undoubtedly true, but whether they have any more tendency to produce crime than a man's stomach I very much doubt I think it has been shown that a well developed dyspeptic is about as likely to go wrong as almost any other class we might enumerate It is not, in my estimation, the fault of the organs that we propose to *excise* as much as it is a fault in the brain that accompanies them, and if you want to get rid of the tendency to crime you will have to excise some of the cells of the brain, if you can find the proper ones, instead of the sexual organs "

THE PHYSICIAN AND THE CRIMINAL

Read in the Section on Neurology and Medical Jurisprudence at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga , May 5-8 1896

BY J B RANSOM, M D

PHYSICIAN TO THE NEW YORK CLINTON STATE PRISON
DANNEMORA N Y

The axiom that the proper study of mankind is man has evidently not long been applied to criminal man, for careful search reveals a striking dearth of records in this regard Until 1841 nothing worth recording had been done in the *special observation of criminals*, and the science of criminal anthropology, strictly speaking, was only begun in 1854, and not until Lombroso's work "The Criminal,' was published in 1876 did criminal anthropology assert itself as an independent science

There are several instances where observations have been published as to the characteristics of criminals, but no connected and definite work was done (*Immediately after the publication of* "The Criminal," however, *numerous works on criminal anthropology were published, especially in Italy*) All the valuable work done in this line is of recent date, good literature in this field is therefore limited and carries with it the conclusion that the whole subject has been surprisingly neglected, and he who would enter this field of work must find himself somewhat lonely On every hand, however, there are evidences of an arising interest in this feature of social life In France, Germany, England and Italy more especially, criminology is fast assuming the dignity that rightly belongs to this important and essential science In our own country, however, no such concentrated results have obtained, and the study of criminal man is a slighted one and the subject little understood More striking is this when we consider that such study is not without necessity, for a glance at the census figures of the United States will show a proportionate *increase* of incarcerated criminals of nearly five times from 1850 to 1890 inclusive

Year	Prisoners	Ratio of population
1850	6,737	1 in 3,442
1860	19,086	1 in 1,647
1870	32,901	1 in 1,171
1880	58,609	1 in 855
1890	82,329	1 in 757

The number of homicides in 1889 were 3,567 in the United States, in 1895, 10,500 This, too, in the face of the fact that society and the courts and general public sentiment has constantly grown *more* lenient, and the number of unpunished criminals has largely *increased*, as for instance, according to Andrew D White, if the whole number of murderers for the six years last past were in prison there would be 40,000, as a matter of fact there are only 7,300 Neither is it because we are unaware of the existence of crime, for it is everywhere present, the newspapers of the day flaunt it in our faces, and our own observations make known to us the existence of a large criminal class, which is surely and rapidly invading every department and function of our social and political life. It is not necessary to enlarge upon this unpleasant feature, it is apparent to every one. The condition confronts us, it remains to determine the causes and apply the remedy, and that without delay. These causes are many and various, but it will only be within my province to speak of those which relate to us as a profession more particularly, and seek to determine just what our responsibilities are in this whole field of scientific and sociologic work.

It would seem that a common interest in the study of man in a biologic sense would have elicited the very best efforts of the medical profession, inasmuch as man has always been the humble recipient of all the experimental work of an aggressive profession since its conception, but that such has not been the case is apparent by the very few medical men who have been engaged in this important branch of science. It may be assumed that this was chiefly due to the fact that in the early history of medicine, the profession of that day were so intent upon the problem of cure, a—to them—much more important consideration than man himself. In a less remote period medical men were engaged in the elucidation of theories, and still more recently earnestly in pursuit of man's common enemy, the microbe, not that this work has not been necessary, and of inestimable value to a common progress, but it does seem paradoxic that its prosecution should have so completely obscured its object, man!

Only occasionally had the physician devoted himself to this work up to the time of Sampson, Lombroso, Forbes Winslow, Camper and Lallemant. It is, however, in our own country that the least attention has been paid to this subject, excepting in isolated cases where men like Drs. Arthur McDonald, Jacobi and Flint, and physicians connected with penal institutions have urged the necessity of criminal anthropology as a branch of medical work. This has been, however, so fragmentary and unclassified that it has not assumed at any time an organized effort in this direction, and therefore has elicited little interest and accomplished less, but the rapid advance in this work recently made in Italy, France, England and Germany, and the alarming ascendency of crime, so diametrically opposed to the progress of our time, the inability of our present administration of the law, and of the penal system to cope with the necessities and conditions of the hour, have forced into consideration of society and government a problem which should have had its solution, or at least intelligent recognition, as paramount to their safety and well being long ago. As it is in the closing years of the nineteenth century with all its marvelous achievements, with all its progress in culture and refinement, society finds itself confronted by a condition which threatens its very existence. Society is finding out that it has nursed or tolerated within its own bosom the upas which may poison it to death. Aroused to a recognition of the fact that such a condition exists, it finds itself in possession of only the crude elements of an embryo science, which to be adequate to these demands must be rapidly developed into one, comprehensive and efficient. Crime and the criminal must receive more weighty consideration by all concerned, or the integrity and strength of our social and political institutions will be subjected (they are already threatened) with serious disaster therefrom. Society has heretofore been content to relegate this whole feature to the courts and the penal code.

It needs no demonstration to show that the modern trial, sentence and punishment of the criminal, so largely based upon assumption and in ignorance of the criminal himself, has measurably failed to protect society from the rising tide of crime. In spite of the exercise of their powers crime has continually and markedly increased. This is in the largest sense due to the fact that the procedures of the courts and administration of law, have based their action upon the theory that its function was first to detect crime, and then to punish it, losing sight of the fact that all men are not alike, and that punitive measures could only be efficient when they take into consideration the individual characteristics and apply the treatment to the criminal's special needs. Intelligent trial and sentence can only be secured when we have a scientific knowledge of the criminal, the nature of his crimes and the natural and social phenomena connected therewith. Such an administration of criminal law can only be obtained by the thorough classification of the criminal into distinct and characteristic types. In the words of Flint. "Before a disease can be treated intelligently it must be diagnosed."

More especially is this true when those types represent physical and psychic anomalies.

I think, in the light which recent investigation has shed upon this subject, that it may be indisputably asserted that crime is often the natural outcome of disease, and that into such causation enter many forms of deviation from the normal standard in both the physical and mental organization represented by arrests of growth, deformities, asymmetries, intercurrent diseases, as well as psychic aberrations and disorders.

This whole subject is at present in a state of chaos, and it is impossible to draw definite conclusions from the data at our disposal, naturally enough as the possibilities of this field have opened up to view, there has dawned upon the consciousness of some the idea that there is such a thing as a natural criminal, and that the commission of crime is not always the result of a long process of evil doing, instituted by telling the first white lie, which precedes the going through of the story book stages of moral decline which go to make up the average romantic criminal. This conception leads them to come hastily to conclusions based upon a few meagre details and incidents and with many learned phrases rush into print seeking to establish the theory that society has made an awful mistake, and assert that crime is and always has been a disease. A great deal is said upon the subject which clearly shows an utter lack of knowledge and a misconception of the whole subject.

All this grandiloquent flourishing of pamphlets and inclination to rush in where wise men fear to tread might well be expected with reference to a science of less than half a century's growth, neither is this limited to the over-enthusiastic for even our most careful students and painstaking observers in the enthusiasm of first discovery have made many erroneous statements and drawn conclusions altogether too arbitrary, but when all this cyclonic agitation of high sounding terms has ceased to confuse our senses, we shall see that these conditions are but the natural accompaniment of the birth of a new science, and that soon from out all this incoherent mass of nebulistic data will be crystallized constructive elements, which when assembled by the skillful and competent men of our time, will constitute a perfected science of criminal anthropology, applicable to the needs of society, and protective of the general welfare In the study of the criminal there has been a tendency to base all conclusions upon anthropologic data, even Benedict and Lombroso have gone so far as to assert the existence of a criminal brain as a distinct type, which I think is unwarranted by what has been derived from still later investigation To these extreme views I certainly do not assent, for in the words of Jacobi, "The criminal can not be considered an entity but as a being possessed of characteristics as various as those of other types of men," neither would I go so far as Rondeau when he states that "all assassins are patients as are all other criminals ' I do not believe that all criminals are diseased in the common acceptation of the term, nor is all crime the result of such disease

Many criminals are diseased and present anomalies of structure as the cause of crime there are however criminals who are so from environment, and from the inhumanity heaped upon them by men There are also criminals of circumstance or accident Neither do I believe that the rogue can be told from the honest man by the shape of his head alone, or by his physiognomy, or the deformity of his jaws, ears, nose, or lips or by any other one of the numerous anomalies we find in all types of mankind, and especially in the types representing the lower strata of society, neither have we as yet the data representing the normal type of man, with which to compare the abnormal[1] When we have we can make more positive statements It is only by the sum total that an exact estimate can be made that is by a careful consideration of all the anomalous conditions which are grouped in and about the criminal, physically, psychically and socially, and a balance struck between abnormal tendency and inhibitory power that a correct conclusion can be reached It is the preponderance of tendency which must determine the character of the individual There is however abundant evidence and well established data to show that crime is largely the natural outcome of disease in the perpetrator, and that by comparison with other men, the criminal class shows a preponderance of anomalous conditions, as for instance, in one of Lombroso's tables of the measurements of the skull we find "that men with normal skulls were three times as numerous among soldiers as among criminals Of men with a noteworthy number of anomalies occurring together, out of 711 soldiers there are only three or four, there were three times as many amongst criminals as amongst soldiers, and there was not one soldier of the 711 who showed an extraordinary number, say five or more," and the same is true of physiognomic, psychologic, and physiologic anomalies amongst criminals

As a rule special anomalies do not necessarily indicate special tendencies to certain crimes, but as stated in my paper, "Shall Insane Criminals be Imprisoned or Put to Death?"[2] in the examination of several thousand criminals, I have been lead to believe that, as a rule, when in the inherent criminal the right side of the cranium, that is, indicating the right hemisphere of the brain in excessive development over the left, especially where there is a marked fulness over the paracentral lobe, the possessor's impulses lead toward homicide I have repeatedly been able to place my hand upon this part of the head of criminals, and designate their crimes to be either assault or homicide without any previous knowledge of their history or themselves

More recent observations have substantiated the above, especially the last criminal executed at Clinton Prison for an unusually unprovoked and brutal murder, the right side of the brain weighing more than the left

"To the student of criminal anthropology, however, every characteristic in the criminal's natural history has an anthropologic, physiologic and psychologic value in itself, and must be a technical study,' that he may arrive at a correct conclusion as a whole, therefore it is not altogether from apparent anomalous conditions alone that he would assume that the man presented a criminal type, or was criminally diseased, for crime is often due to intercurrent disease, especially to chronic diseases of the heart, meningitis, tubercculous disease, and syphilis, criminals are especially prone to diseases of the heart Out of 2,011 men examined by myself in a general way on admission into prison, 239 had gross heart lesions, and many more obscure and less important ones I should estimate that 25 per cent of all criminals would show disease of the heart or of the great blood vessels When we consider the relation of the heart to the circulation of the blood in the brain, we shall understand how a diseased heart can produce brain disturbance Meningitis is also a prolific cause of crime, especially those of assault and homicide, this is particularly noticeable in the latter It is not necessary for me to refer to the maniacal tendency due to inflammation of the meninges Any one who has conducted a patient through the several stages of a meningitis, knows well the effect of the disease upon the mental condition The result of meningitis is often a thickened patch, a softened area, or a circumscribed adhesion, any one of which is capable of driving the unhappy possessor to the most fiendish acts of violence, as the spur to the horse, it urges on the diabolical impulse In autopsies upon criminals who had committed assaults or homicides, it is very seldom, if ever, that some such thickened patch or atrophic area has not been discovered In my last case the adhesions were extensive M Dally, from a twenty years' experience, says that "all criminals who have been subjected to autopsy after execution gave evidence of cerebral injury, often undiscovered prior to autopsy ' From my own experience I believe this injury is usually the result of some form of meningeal inflammation Syphilis is well known to cause grave neurosis, and among criminals a very large percentage are syphilitic The effects of syphilis upon the brain, either in the deposit of gummatous tumors, or in the production of degeneracy of brain tissues, is a prolific cause for mental disorders, especially of a temporary nature I have seen a number of criminals who were, no doubt so, from the effect of syphilis, or its injudicious treatment Tuberculosis is also a prime factor in the problem of crime Many a man is a criminal because of the presence of tubercular toxins circulating in his brain, or to the poverty which this inability to earn his livelihood brings him Almost every physician is familiar with what is called the insanity of phthisis Several other diseases are distinct causes for crime, especially those connected with the genito-urinary organs

---

[1] It is encouraging to know that there is a decided movement in the endeavor to establish a normal structural gauge for men by the use of instruments and technical observation

A large amount of data might be offered which would go to establish the fact that a large proportion of crime is the direct and natural outcome of some form of disease I shall not enter into detailed minutiæ or technicalities, neither shall I weary you with an array of craniometric figures and anthropologic data, for such information is best found in the works of Benedict, Lombroso, Lacassagne, Ferri, Ferrero, Garofalo and Dugdale, but simply attempt in a general way to institute a discussion of the relation of the physician to the criminal problem I shall also purposely avoid the sociologic aspect only in so far as is necessary to define this relation

If it be conceded that crime is the result of disease we shall have a conception of the criminal, which at once changes the whole application of the principle of treatment, revolutionizes sociology and annihilates many of the more primitive methods of the administration of so called justice Surely all efforts should be directed not toward inflicting upon an already unfortunate individual still greater misfortune, but in assisting him to overcome his infirmity Now if this was true of all criminals, and if the question of degree did not enter so largely into the problem, the whole matter would be simplified, there are, however, questions of degree and questions as to what proportion of crime is due to disease, recognizable and estimatable Herein lies the opportunity for the exercise of large common sense, and in the consideration and treatment of the whole subject, let us be guided by it

Much confusion arises from false notions as to what the criminal is Too often the criminal is considered an abstract quantity, as if belonging to a different order of beings, such is not the case however, they are men and women, creatures of hope, of longing and of fear Our ideas of the criminal should not lead us to think that the mere fact of putting a man behind the bars and habilitating him in stripes, at once assigns him to a different species, for it will be found that the criminal is much like other men, amenable to treatment and improvement The distinction which criminologists would make in the theory that the criminal is of degenerate type, does not apply to the incarcerated criminal alone, but also applies to millions who have never seen the inside of a court of justice, or felt the dampness of a prison cell There is no distinction from a psychologic or physical standpoint between the incarcerated and the unpunished criminal, other than the results consequent upon his environment

It is because the conditions which enter into the criminal make up that lead to the commission of crime are not better understood, and the naturally fallacious conception as to what the positive school of criminology advocates in the scientific treatment of crime, that efforts looking toward the improvement of our methods of treating the criminal are so fruitless The positive school of criminology does not desire to divorce the criminal from his responsibility to the law, or mitigate the punishment of crime, which is its inevitable auxiliary, it proposes to punish crime, not, however, in a retaliatory or vengeful way, but, in so far as is possible, use its punishment as a means of restoring the offender to his former rectitude before society and the law, recognizing "that crime is not always of the free will, but rather a natural phenomenon which can only disappear when its natural factors are eliminated" It seeks rather to adapt measures to conditions rather than attempting to make conditions fit measures, and recommends a plan of treatment based upon the classification of the criminal resting upon scientific anthropologic data

Equally fallacious notions are entertained as to what is the part of criminal anthropology in the scientific treatment of the criminal The modern criminologist does not seek to base conclusions upon anthropologic data alone, but as Ferri puts it "All that he seeks of anthropology is this—Is the criminal, and in what respect, a normal or an abnormal man? And if he is abnormal is it congenital or contracted, capable or incapable of rectification?" This is all, but sufficient to enable the criminologist to come to positive conclusions covering the measures that society can take to protect itself against crime This then is the summing up of the whole matter 1 A correct and efficient treatment must rest, as in all other departments of human affairs, upon the proper classification as a primary and essential step to proper observation 2 That such classification to be of value must rest upon anthropologic data 3 Inasmuch as anthropology is scientific and positively medical, the essential work of classification naturally falls within the physician's province, and can alone be performed by him

Not only is the object of classification to admit of a more intelligent study of the criminal, but it is through such classification alone that proper treatment can be administered

The classification of the criminal also predisposes the necessity of proper classification and grading of penal institutions, so that when the criminal has been assigned to his class by the courts, he can receive the treatment best suited to his individual requirements, the insane or weak minded criminal should be sentenced to a hospital for the care of the insane, the born or habitual to an institution specially calculated to care for confirmed and incorrigible criminals criminals of passion and occasion, to short term institutions where they could receive treatment looking to their reform To accomplish this all of these institutions should be graded to facilitate their special study and treatment The criminal having in him the possibilities of reform should have opportunity for such reform The confirmed and hopeless criminal should be excluded from society permanently This phase of the criminal's treatment is more explicitly treated of in my pamphlet published in November, 1895, "The State and the Criminal"

Having been properly graded, every institution devoted to the care of the criminal should be provided with a physician specially qualified not only for the proper care and treatment of the ordinary ills of the criminal, but abundantly able to conduct a proper study of the criminal based upon anthropologic data and criminologic factors Not only will such efficiency ensure proper grading and intelligent treatment of the criminal, but it would furnish to the science of criminology valuable data upon which to base still further conclusions The first step in the classification is the appointment to every criminal court of a competent physician to assist the court in determining expert questions relative to the criminal's physical and psychic condition at the time of trial

The physician in this work of classification should bring to his aid all instruments of precision necessary to the proper measuring and estimating of the criminal from this standpoint such as the sphygmograph and craniometer[3] This would only apply to cases not having been previously examined and recorded

First in the proper classification of the criminal is his division into two great classes, curable and incurable, in so far as results are concerned, this covers the whole ground, but that such a division can be correctly made, necessitates the classification of the criminal with reference to his type, especially in the application of treatment to that numerous class of curable criminals I have therefore adopted as a most useful classification that of Ferri, which divided the criminal into five classes, to wit 1 The insane criminal 2 The born criminal, 3 The habitual criminal 4 The occasional criminal, 5 The criminal of passion

It will be found that this classification meets the largest requirements possible under our present knowledge, but unmixed types of criminals are unknown and criminals can not be precisely classed under certain categories for they frequently exhibit mixed propensities, and merge from one type into another And in one some of the characteristics of several types may be blended This classification, however, is a practical one and based upon sound observation

The Insane Criminal —There can be no scientific distinction made between the criminally insane and the insane criminal The distinction is only an associate one and refers to conviction True criminal science knows no distinction between the incarcerated and the criminal at large To him the abnormal condition which controls a criminal act, constitutes the criminal identity The courts have shown their utter inability to differentiate between the insane criminal and the ordinary If a man has within him a tendency sufficiently strong to cause him to commit offences against person or property, he is a criminal, and if such depends upon an abnormal mental condition, he is an insane criminal, the only distinction necessary to make is in a penologic sense, and that is the distinction between the insane convict and the insane criminal The question turns upon the point of insanity related to responsibility under the law To be able to distinguish between the born criminal with abnormalities of structure and psychic disturbances, and the insane criminal, is sometimes a difficult thing to do, and I can not agree with those who deem it an easy matter to decide, so intimately mixed are the inherent tendencies and anomalous conditions present in the two types, so frequently the same conditions are manifested in both that it is sometimes very difficult but not necessarily impossible

Garofalo's distinction is a good one, and is applicable to a large number of cases He makes the distinction, 'with the insane criminals, that in the act itself lies the satisfaction, not the object, while with criminals the act is only a means to an end" To the former crime is a pleasure, to the latter a paying business necessitating, it may be, disagreeable acts

Criminals of unsound mind can not all be classed in the same category if we are to study them intelligently indeed, it is difficult to make a classification which is always distinctive

For my own convenience I subdivide insane criminals into five classes

1 The paranoiac, who are persons exhibiting self exaltation, systematized progressive delusions, writers of insane political documents, and with tendencies toward political homicides which are usually consistent with their delusions Guiteau and Prendergast are good examples of this class

2 The psychic epileptic A class not numerous and who commit the unexplainable murders This class of criminals commit outrageous murders during epileptic seizure, and which seems utterly inconsistent with the circumstances and the perpetrator, and can not be judged by the ordinary psychology of criminals (Ferri)

3 The phrenasthenic or psychopathic criminal, who is one of irresistible impulse, feebleness of will, and with morbid tendencies to private murder This class of criminals commit atrocious crimes, apparently without motive and purely from the force of impulse, or from the satisfaction of the criminal act itself Good examples of this class are Jack the Ripper and Mrs Halliday

4 The morally insane or reasoning phrenasthenic The only difference between the morally insane or reasoning phrenasthenic is the absence of delusions, and their perversions are of the sentiments and affections (Regis) "They represent a small class and are the individuals who apparently with full reason and judgment commit themselves in an unconscious and frequently paroxysmal manner to indulge in errors of conduct and immoral acts which are really pathologic, and although apparently less insane they are more profoundly degenerate than the delusion cases, and have a more marked degree of mental infirmity and imbecility '

The fifth class of insane criminals "consists of a large body of persons tainted by a common and clinic form of mental alienation, all of whom are apt to become criminal This class of insane criminal are sometimes identical, and sometimes opposed to the born and occasional criminal" (Ferri) This class commit various crimes under insane impulses and are commonly degenerates It is seldom that a criminal of this class commits an atrocious crime unless under an impulse of passion

These classifications are more a matter of convenience and should not be arbitrary, practically, the whole importance of the determination of the criminal insanity or sanity devolves upon the question of responsibility, and classification is only useful in arriving at correct conclusions as to the individual's responsibility under the law

The Born Criminal —The born or instinctive criminal is one who most frequently presents anomalies of organization and psychic aberration, they are criminals the same as other men are mechanics or artizans, and look upon the penalties of crime as the natural risk incidental to the business, who do not regard a crime from its moral aspects, but simply from the risks attendant upon its execution The born criminal as a rule is deficient in both moral and physical sensibility This criminal insensibility is manifested in his perfect inability to see the evil side of a criminal act, and to forecast its effect upon himself as a moral entity, also in his indifference to consequences and to feelings of remorse He plans and executes with the whole moral code left out, only as it is used to escape the penalty which may deprive him of the exercise of his craft

The lack of physical sensibility is often marked

---

[3] The time will no doubt shortly come when hypnotic suggestion and the use of special instruments for the measurement of brain impulses, as related to physical conditions will be added to the physician's armamentarium

My attention was first called to it particularly while doing operations upon this class of men, they exhibiting no evidence of pain even though the operation might be painful and to the normal person excruciating One man attempted to castrate himself and when discovered had succeeded in exposing the testicle, having opened the scrotum throughout, and was about to cut the cord This same man under a previous operation for ligation of the radial artery had shown almost perfect insensibility to pain Another case was that of a man about 30 years of age, in good health classed as an ordinary convict, quite inoffensive, but who was drawn into an altercation with a fellow workman in the repair shop, and who in a fit of rage walked deliberately across the shop to a small circular saw, threw on the belt, and without hesitancy placed his forearm upon the carriage and sawed it completely off just below the elbow joint He seemed perfectly indifferent to the whole affair and to suffer no pain He was discharged from prison, was again incarcerated, is now serving a second term and is still considered an ordinary convict Numbers burn themselves in a most horrible manner to get rid of doing a moderate task, cut off their fingers and mutilate and injure themselves in different ways to carry a point, not because they could endure pain heroically, but simply because they had learned that these things did not hurt them overmuch This insensibility to pain tends to rapid healing of their wounds There is, however one erotic type of born criminal who is over-sensitive to all sorts of pain and suffers exaggeratedly from the slightest injury This moral and physical insensibility at once places the possessor in a low order of organization and one largely incapable of reformation or improvement From this class will always come the major portion of incorrigibles

The Occasional Criminal —The occasional criminal presents rarely marked anomalies of structure such as characterize the born criminal This type are more criminals from environment and circumstances, and do not present those anomalous conditions that bring them properly within the province of a medical study, they are therefore best left to the sociologist, only in so far as individual cases present psychic and physical diseases requiring medical treatment

The Criminal of Passion —The criminal of passion is one of irresistible impulses, who under the stress of uncontrollable passion commits crime of which there has been no premeditation, and for which he suffers the keenest remorse "He is usually strong enough to resist ordinary temptations, but does not resist psychologic storms which are sometimes actually irresistible" They are of highly neurotic type, and their study is of interest and consequence to the physician in that they approximate criminals of unsound mind, and it is often a question to determine as to the sanity of their acts They are not criminals in the true sense, but rather offenders, victims of their own impulses

We come now to consider the physician's relation to the criminal as regards his treatment The complete study and treatment of the criminal must ever be largely a sociologic one As has been said by Lacassagne "The criminal is a microbe inseparable from his culture broth the social surrounding" And gradually but surely the purely anthropologic study of the criminal has given place to a plainly more sociologic one based upon it

The treatment of acquired and intercurrent disease of the criminal falls almost entirely within the field of labor of the physician to penal institutions and should embrace in its operations all of the medical, surgical, mechanical and therapeutic means at the disposal of the physician In the treatment of heart lesions so numerous among criminals, both gymnastic exercise and proper medicaments should be used

For syphilis, constant specific medicaments and operative procedures should be used, and the same in meningeal lesions Tuberculosis rigid isolation, with the destruction of the bacilli by every modern means, and climatic influence should be a part of the treatment The various manifestations of psychic disorders and abnormalities should receive generous treatment by means of spray baths, surgical shock and electricity At Clinton Prison, New York, all these therapeutic means are in active operation with beneficial and successful results Aside from the treatment of the physical ills mentioned, it is with the insane, the born and weak-minded criminal that the physician will have the most to do in the treatment of psychic disorders and the development in him of the power to control brain impulses

The treatment of the insane criminal falls entirely within the sphere of the State Hospital for the Insane The chief office of the physician with reference to the insane criminal is his classification and isolation This function as now exercised is chiefly directed toward the examination of the criminal when accused of crime, and is a medico-legal one, and one which is not to the credit of our profession, which I set forth in a paper read before the Medical Society of the State of New York in February, 1895 "Shall Insane Criminals be Imprisoned or Put to Death?"

I am pleased to be able to state that there is a good prospect of remedial legislation in my own State regarding the exhibition of medical expert testimony in all criminal trials

It is not, however, so important to the protection of society that the insane criminal receive just and equitable treatment in courts of justice, as it is that he be apprehended before he is able to accomplish the execution of his delusional impulses It is the apprehension and detention alone that can protect society from their depredations Had Guiteau and Prendergast been apprehended, both Garfield and Mayor Harrison might still have been alive

We should urge the passage of such laws as would tend to place some competent medical officer in every community as having the right of surveillance with reference to this type of mankind

In the treatment of the born and habitual criminal, the first object should be to increase inhibitory power The will may be said to be the gateway of the mind, and through its narrow portals pass impulses for good or evil, wise or foolish, and it is the exercise of this faculty that must control the tide of psychic impulses that seek to find passage to the outer world Since inhibitory power is the essential factor, the cultivation and strengthening of this power should be one of the chief objects of treatment in the weak-minded and degenerate criminal, the exercise of certain brain functions over and over again constitute a habit of action which becomes routine and natural If the will is to be strengthened and habit broken, new tracks of association fibers must be brought into play, dormant brain cells stimulated into activity and the whole current of thought and cerebration revolutionized This can only be accomplished by some sudden shock, either physical or mental

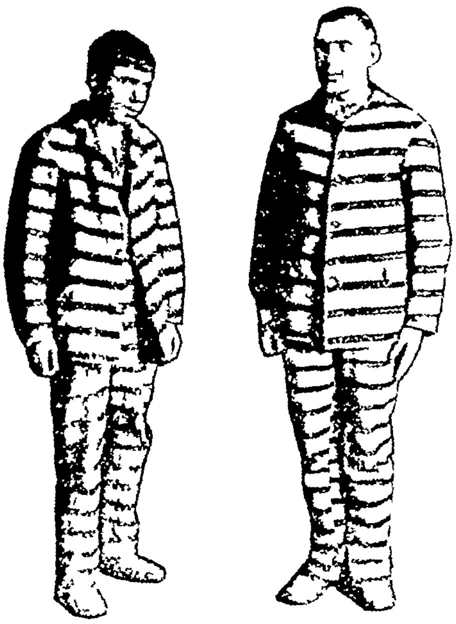
It is a well-known physiologic law that by severe mechanic shock we can suspend the function of cell groups, partially or entirely It was to this principle of shock that were due many beneficent effects from the use of the more primitive forms of physical punishment in corrective institutions It is a well-recognized fact by penologists that the shock attendant upon corporeal punishment has often resulted in the cure of certain psychoses Many a man has been converted from an intractable crank on the border line of insanity into a tractable and useful one

I find this view is substantiated by the figures relative to the commitment of insane convicts to the State Hospital for Insane convicts, which, prior to the abolition of corporeal punishment in the prisons of the State of New York showed 00874 per cent and since its abolition up to the present year 01764 per cent, or more than double the former percentage While these figures can not be relied on as alone affected by this change, they are sufficiently indicative of the relation existing between the two, since apparently the contributing circumstances would rather tend to lessen the number of commitments than to increase them I am not using these figures for the advocacy of corporeal punishment, but simply to show the influence of shock in preventing mental disease In the application of all the forms of shock the effects are produced by the pedagogic impression made upon the brain, which in the class of criminals under consideration is always weak and incompetent, and whose brain cells respond more readily to stimuli applied through physical sensation

In a paper read before the Medical Society of the State of New York upon craniotomy in idiocy, in January, 1895, Dr Charles L Dana attributes the benefits derived from operations upon the skull for this condition as due chiefly to what he terms "Surgico-pedagogic influences" My own experience has substantiated this view with reference to weak-minded and degenerate criminals My attention was first called to this in observing that in certain cases where criminals had been severely handled in fights, and where the shock was considerable, and especially when associated with extensive scalp wounds, that these men usually became more tractable afterward and evinced marked changes in many ways during the remainder of their incarceration

In several of these cases there was an almost complete turn about in the disposition and psychic condition This led me to investigate, and I found that by freely cutting through the scalp down to the bone, and raising the periosteum, still greater improvement followed I have now begun a series of operations upon neurasthenics and weak-minded criminals April 1, of this year I operated upon a young man, aged 22 years, serving a first term in State prison Operation for relief of neurasthenia and excessive masturbation Patient was extremely nervous, sleepless, despondent and apparently becoming demented The hair was closely shaven, and under antiseptic precautions the operation was performed as follows Two horse-shoe incisions were made five inches in length, one on the right and one on the left side of head, one and one-half inches from the median line at the apex of the cranial arch The periosteum was cut cleanly through, and separated from the bone for a distance of about one inch all round the incision, grooves were then cut in the bone, but no bone removed, the wound was packed with iodoform gauze and dressed ordinarily The wounds were then packed loosely until they healed by granulation No sutures were put in The effects of this operation were like magic, the young man improved in every particular, slept well, appetite improved, figure became erect, took on flesh rapidly, circulation improved, and his whole aspect was very much more vigorous The habit of masturbation was entirely relieved I show you photographs of the young man before and fifteen days after the operation Prior to this I had circumcised him, and used all other means at my disposal to effect the cure of his habit with negative results (This operation is also beneficial in meningeal inflammations, and also with thickened and adherent scalp areas) This principle has for a long time been recognized in isolated and incidental ways, but never to my knowledge has it been understood thoroughly or applied in any systematic manner

Here is a wide field for study and experiment, and I believe that much can be accomplished in the treatment of this class of criminals by the application of some form of shock I am contemplating the construction of an electrical apparatus, which will produce the maximum amount of shock and physical impression with a minimum risk of injury Any means by which powerful influences can be brought to bear upon the subject will offer the best and most favorable opportunity for improving the patients



Before operation After operation

J R, Aged 22

The treatment of the occasional criminal, and the criminal of passion does not require special enumeration

The application of scientific principles of classification and treatment of the criminal considered from a sociologic standpoint, is one fraught with difficulty and we need not flatter ourselves that apparent good results will come quickly or that the way is easy, the duty is plain however and we must walk therein It has ceased to be a matter of choice and we must be equal to the responsibilities which this new field of action enforces Already in the half century of its life, the science of criminal anthropology has recorded brilliant achievements in the accumulation of invaluable data and the elucidation of many valuable truths These achievements have come largely through the labor of medical men, therefore the soundness and efficacy of this relation of physician to the scientific treatment of the criminal can not be doubted, nor that it falls properly within the medical province, for if we interpret aright the significance of the astonishing developments of our time and note correctly the movement of modern medical thought and action, we shall come quickly to the conclusion that the field of medical work and practice is rapidly widening and that its mission can no longer be so entirely restricted to the narrow limits of the treatment and cure of disease, but more to its diagnosis and prevention, and its future accomplishments must comprehend much more that appertains to the safety and welfare of the people Through the gateway of laboratory work in our own profession, and the investigations of the correlative sciences, a great flood of light has come, old systems are breaking up, relations are changing, new adjustments are in order, the X rays alone is likely to revolutionize the whole rationale of diagnostic, *prognostic* and operative procedure He who shapes his course by the experience of the past alone will soon find himself deprived of the needful appreciation of an enlightened public The profession must take to itself larger spheres of action, must extend its powers, must put itself in harmony with new conditions, its relation to society and the community at large must be better understood The physician is to become a mentor to the people, and his efforts like those of his time must look to the improvement of mankind, not in the concoction of monstrous formulas, or in the combination of nauseous decoctions, but in his knowledge of the causation and the exercise of his powers in the prevention of disease and the general guardianship of the home, the individual and the public So far as this function has been exercised it has accomplished much good and has been of incalculable benefit to society at large, in the protection of our shores from pestilence, our municipalities from infectious diseases and the securing of abundant *opportunities* of health ful living the labors of our profession have been untiring, fruitful and reassuring

The opening of this new field of criminal anthropology and sociology, embracing the type study of man, and the resolving of society into its respective classes offers equal opportunity for the exercise of high and noble powers

It is only through the exercise of such a prerogative that the physician can sustain the position in which the evolutional processes of scientific progress have allotted to him, and he will only rise equal to the dignity of this requisition when he shall have assumed the rôle of a competent student of the bio psychic principles and elements which enter into the different types of criminal man, and society be enabled to protect itself against crime, a protection too long and entirely entrusted to the offices of the penal code

DISCUSSION ON PAPERS OF DRS CORR AND RANSOM

Dr D R Brower—In Illinois, our State Society and our various local societies have, during the past two or three years, had this question before them on various occasions, and what is true of the State of Illinois is true of many of the other States The question of crime is not a legal question it was until twenty five or thirty, or possibly forty years ago, a purely legal question, and to day in its practical application it is a purely legal question, but in reality it is a medico legal question, and, as a consequence of the utter failure of the law and the church to stay this criminal procession, we have the results, the vast, marvelous, everwhelming increase of crime The only thing that can possibly stay this great increase is for the medical profession to step to the front and teach the intelligent laity that the care of the criminal is as much a medical as a legal question There are some things that study of this question has satisfied me as being established 1, the increase of crime, 2, we state as the cause of this increase of crime a vicious parentage, bad environment, alcoholism a constant increase in the urban population and last, though not least, the *unreasonable manner* in which the laws are administered, 3, that the habitual criminal is an abnormal man, which is shown physically by asymmetry in cranial cerebral development and in physiognomy, as well as by anomalies, in physical sensibilities and in motor activites One of these anomalies does not make a criminal man, but in the habitual criminal these abnormalities are present in a vastly greater amount than in any other person in the community There are psychic abnormalities manifested by a moral sensibility This is most mani*fest and* almost universal, not limited to the moral criminals, but prevailing throughout the whole great class, leaving out the few who are classified under the occasional and passionate criminals There is a lack of forethought with them, they live simply in to day And there is a low grade of intelligence, a prodigious amount of vanity, and an emotional instability The practical part, upon which the laity must be intelligently educated, is what to do with them—how to treat them The question is a medico legal one, and the doctors must come to the assistance of the church and the law The social and bio logic condition of the person, and not the accident of crime, should determine the degree and kind of punishment As our laws are adminstered to day, if the theft is a trifling one, the punishment is but slight, if the amount taken is a large sum, the punishment is accordingly great The reference is not to the criminal, but to his crime, whereas the crime is a mere incident, as the theft was $5 because there was not $5 000 to steal The measures that are to counteract crime must be, not according to the crime itself, but to the condition of the criminal

In my studies of this question in the institutions of my own State I found a woman who had been sentenced to our *Bride*well thirty times She should have been sentenced but once, and the county of Cook would have been saved the expense of twenty nine arrests, trials and imprisonments, while the community round about her would have been saved a great deal of perplexity and considerable destruction of property She had upon her, as plainly marked as any habitual criminal ever had, the physical and psychic stigmata of degeneration

It is this unreasonable administration of our laws that has probably more to do than anything else with this marked increase in crime I would like very much, if it is practicable, to have attached to every court some person who is skilled in criminal anthropology who can aid the court in determining what the sentence shall be The rule that has been adopted in some of the courts of Illinois so far as the reformatory institutions are concerned, has been that of indeterminate sentences, and consider this is a much better plan If the indeterminate sentence should be applied to all criminals, and the investigation of the anthropologic condition of the criminal made *in the* institution to which he is consigned, vastly more beneficial results would *follow* than by his investigation during the trial

It is by indeterminate sentences that I think the matter can best be settled The only trouble in the State of Illinois, so far as the reformatories are concerned, is that the maximum limit is not enough in every instance In the next place a very serious interference with the suppression of crime is placing the pardoning power in the hands of the governor It should rather be placed in the hands of a *commission* skilled in the subject of criminal anthropology

The plan of disposing of these criminals just before and during the trial is a mistake These supposed criminals are sent to a common jail and the associations of that jail are vile, and the man who has not yet been declared a criminal by the law is there thrown into contact with confirmed criminals This is very wrong There should be established in every community detention places where there can be a separation and isolation of these criminals awaiting trials, and then, when the sentence comes, there should be three classes of institutions to which these people are consigned A reform school for the juveniles, reformatories for the curables, and penitentiaries for the incurables

Some of our laity think that this medical disturbance in the matter of crime is for the purpose of relieving criminals of the penalties of crime Such is not the case First to protect the community, first to see to it that these criminals, once arrested, should be kept in custody until they are cured, that is the most important point

It is only through such societies as this, through medical men and women, that the laity can be educated up to a proper appreciation of this great question We are going through now precisely what was gone through at the beginning of the century, or a little before, in the matter of insanity, when that was divorced from the custody of the church and the law

We are to day pupils in this work of reformation, and very soon the same results will be accomplished with reference to the care, treatment and the cure of these criminals—probably not to the same extent, but similar results will follow as have been seen in the care and the cure of insanity

DR JOHN PUNTON—There is no doubt that there is a great lack on the part of both the medical and the legal professions in failing to handle these cases properly These changes which are proposed, however, would mean an entire subversion of the constitution of many of the States of the Union, in other words, the present status of the legal adjustments of crime would be undermined and that is a very large matter for the medical profession to undertake to do I am in the main in favor of the reforms outlined, and just in proportion as we agitate this matter we are aiding not only the legal profession but also the community in which we live

DR CAMPBELL—That law and the church have failed to repress crime is well known, it is now proposed that we of the medical profession shall take hold of it The alarming increase in crime is known to us But I do not entertain any sanguine anticipations of the doctors doing much more than the church and the law have done, if so much This great increase of crime can not be attributed to the causes that have been assigned to it, so far as I have heard here to night We have always had bad education, syphilis, alcohol, bad inheritance and bad environment In my opinion this great increase of the criminal class is owing to the advance of our civilization, the increase in the species, the growing stress that has been brought to bear upon the means of gaining a livelihood These forces are irresistible They will continue, and crime as the result of them will continue, and if all these admirable suggestions are carried out, I doubt if 5 per cent of the crime will be stopped

DR POWELL—I think the commission of experienced men would be a very desirable thing to have

DR QUINBY—If we study the results of imprisonment, we see the victim, instead of being benefited by punishment, made worse by it This is due to the method and management of our criminal jurisprudence A young man who was well disposed, whose environments were correct, whose education was proper, whose bringing up was right, but who became involved through alcoholism, was thrown among the class of hardened criminals when arrested, and from that hour, he was kept there six months for some slight offense, he has become a degenerate man He told me that his barbarous treatment during his confinement is what sent him downward Now, could that man have been arrested and treated somewhere instead of being thrown into prison, if we could have institutions for treatment, not simply for imprisonment, the results would be different

These are all abnormal cases They are sick, and how do we treat them—as mentally and physically defective? No Cruelly, inhumanely, putting them with criminals, into the charge oftentimes of men who are themselves brutes

The criminal classes in this country are largely increasing, and something must be done to stop this increase The church is not in a condition to do it, because these individuals are sick people, defective physically and mentally, the power of alcohol always having a tendency to destroy will power, hence, the physician is the proper man to give advice

DR BISHOP—We feel a little sensitive when the preacher and the public blame us about things, and we are in the same position exactly when we blame the church and the community We are part of the church, or should be, we are part of the community, and as citizens we are responsible There is a great deal of hypersensitiveness on the part of our good friends who believe that these criminals as a rule are defective It seems to me that very often they are liars

I think a slight change in the law would be of advantage, on the basis of sentencing to prison for a determinate period, and if at the end of that time they were not cured, and still unfit for freedom, to keep them in prison for an indefinite period until they showed that they were fit to be released

It is an outrage to send men to prison and have them resort to all sort of crime that it is possible to do inside those walls, and then set them loose on the world at the end of the time for which they were sentenced The mistake is that they are not made to feel that they can gain something by improving

There is no question that men are morally deficient as they are mentally and physically lacking, and the proper place to treat them is in some school for development

DR CORR—The question is how to prevent crime, how to prevent the young person who starts out with a small degree of tendency from cultivating that tendency and from becoming a criminal We must improve our society so that we do not have any of that class born Dr Ransom has classified crime very finely, but we want a classification which shall tell us how to prevent it Now, if it be true that the conduct of people is guided and inhibited by the moral sense and that is a faculty of the human mind that is capable of cultivation, I ask you to formulate some plan by which this end can be accomplished

THE PSYCHOLOGY OF NARCOTISM

Read in the Section on Neurology and Medical Jurisprudence at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5 8 1896

BY W XAVIER SUDDUTH, A M, M D

CHICAGO ILL

Nature intended that man should be a comfortable animal and enjoy to the full the fruits of his labor

Man has ordered otherwise, and as a consequence in the receding days of the nineteenth century, when art and intellect have reached their highest development, we find man, born to be the favored creature of nature, laboring under self-imposed burdens of society, oftentimes heavier than he can bear As a natural consequence of his pernicious environment he is frequently found seeking surcease from the pains of existence in self-immolation, temporary intoxication or suicide, the method adopted depending much upon his belief in a future state and his relation thereto

What are some of the steps that have operated to bring about these deplorable conditions? They can not be laid to natural causes because there has never been a time in the history of civilization when the actual needs of man were to be satisfied with as little expenditure of vital force as at present The cause of the stress of the age must therefore be looked for, not in the physical, but in the psychic domain of man's nature, and it is to this phase of the question that I desire to call your attention to-day

In that degree that man is able to perform the necessary duties of life by force of habit so does he lessen the labor of existence The hardest work man has to do in this world is to think Every psychosis has its neurosis New experiences or acts are successfully mastered only by the expenditure of thought The greater part of the absolutely necessary acts of existence are performed by rote rather than by thought Thought labor requires nerve action, just as surely as locomotion incurs muscular activity, and while it is true that there is a marked physical difference between mental and muscular action, yet physiologically considered they both express a condition of catabolism that has to be met by metabolism Ordinary cell wear is not necessarily painful On the other hand, a certain degree of pleasurable exhileration accompanies most necessary bodily functional activity When, however, exercise is carried beyond a certain point, so as to become forced, it soon becomes painful When weariness ensues as a consequence of functional activity, pleasure ceases and pain begins Pain is the absence of pleasure according to our major premise laid down in the opening sentences of this paper, and if this be true, then its abolishment does not consist in self-immolation, but in a readjustment of our relation to our environment or its more or less complete reconstruction

Pain and pleasure are not distinct physical conditions, no matter how intimately they may appear to be related, but mental states, and therefore require careful consideration to differentiate them Pleasure and pain are often so closely connected that it is with difficulty that they can be separated Not only this but the terminology used to express the two conditions is inextricably confused Many people are said to "cry for joy " In fact, so narrow is the division line between the two conditions that the scale turns upon the mental state of the individual at the time of experiencing any particular sensation, as to whether he suffer pain or feel pleasure The close relationship between them is thus shown by a case in which the one merges into other Continuous stimulation that at first gives pleasure, in time becomes painful This leads to the conclusion that only a certain amount of pleasure is bearable by human nature, if furnished without intermission The system may be surfeited by pleasure as well as borne down by pain But what is it that suffers? Surely not the physical that alone experiences wear No! Pleasure and pain are not conditions *per se,* but mental perceptions of sensations experienced at the time or revived from some previous experience, through thought images brought before the mind by association of ideas Then again, not only does pleasure easily merge into pain but the very absence of pain to him who has suffered, is a pleasure The fullest appreciation of the pleasures of existence are to be had by comparison with painful experiences happily passed While many of our joys and sorrows are the result of purely physical sensations, yet a considerable proportion of our pleasures and pains are intimately associated with our emotions and are distinctly dependent upon the peculiar physical condition in which the experience finds us Many of the acutest pains of existence are those of restriction Man longs to be free, to cast off the burdens of care, for even a short space of time, to secure a respite from the pains of existence—to lose himself hence his resort to the use of narcotics Sad delusion! The greatest slave of all is he who seeks his freedom in these deceptive agents Nine out of ten narcomaniacs will tell you the some story, when asked as to how the habit was formed "I took it to relieve pain,' "to drive dull care away," "to get a little rest, ' and thus the chains of habit were forged

Dr Carpenter says, "that our nervous system grows to the modes in which it has been exercised " That is only another way of putting the fact that we develop along the lines of least resistence, according to the bent of our special inclinations, limited and modified by our peculiar environment Habits are more easily formed in youth than later in life, by reason of the fact that the organism is in the formative stage and the inhibitive feature of the will is less developed than it is later on If a young man or woman reaches the age of twenty without having acquired any vicious habits of thought, action or appetite, ten to one they will go through life free from contamination Nevertheless, physical states of weakness later in life seem to unman the individual and reestablish, to a greater or less extent, the conditions prevailing in adolescence Drugs that may be given during the crisis of a disease with impunity, if continued during convalescence are apt to give rise to drug habits, hence the necessity of discontinuing the use of stimulants and narcotics during this stage of the disease and depending upon a nutritious diet and natural remedies to bridge over this critical period when the will is weakened and the moral faculties seem to be more or less clouded

Narcomaniacs may, for convenience of study, be divided into three classes

1 Those who have acquired the habit through hereditary tendencies, and who find in the use of narcotics a physical pleasure

2 Those who, though physically strong, yet are *led into the habit by social customs as the result of* environment

3 Those who turn to narcotics for relief of the pains of existence

The psychologic bearing of the several classes is essentially different when laboring under the spell of the drug Members of the first class have, in most instances, the warning example of degenerate ancestors, yet so great is the demand of the system for sedation that they brave the dangers and public opinion with a brazen effrontery that is many times astonishing They have no desire to reform and their course is continuously, progressively downward With them there is no shadow of turning They are wholly given over to evil ways and the sooner they end their days the better for themselves and mankind at large

The second class, considerably larger *than the first,* much larger in some countries *than others,* suffers mostly *from the direct effect* of the drug because removed from the moral stigma under which other classes labor While its members are seriously handicapped in the battle of life yet they manage to preserve a tolerable existence unless the particular narcotic used happens to be hasheesh or opium, and even against the latter the natives of [illegible] seem to hold a more or less charmed existence

It is to the third class, however, that I desire to call special attention, because they are those who dwell among us Our fathers, mothers, brothers, sisters and friends Brought to their condition of enslavement many times by circumstances over which they have no control, held accountable by an highly intellectual and moral civilization, they suffer, not only from the direct effect of the drug used, but from the goadings of an outraged moral nature The members of this class, oftentimes forge their chains through years of petty indulgence in the use of the milder sedatives and narcotics Their case then is one of slow growth and needs to be studied from that standpoint A diseased condition of the will is established, in which the individual finds himself unable to stand out against what he knows to be sin against the physical body It was not always so there were times when, in the early history of the case, had he had the right kind of treatment, he could have broken the bonds of the growing habit with comparative ease These diseased conditions of the will form most interesting psychologic studies and promise to throw much light upon the rationale of treatment In the main, an entirely erroneous idea of the function of the will prevails Most persons consider it as a direct motor force only, confusing it with volition, which is the act of the will, and thus overlook entirely its inhibitive aspect In one sense the will may be said to be dual, but in any event it represents a state of the mind, and is, according to James, " a memory of past acts " Its parents are desire and feeling and its offspring are represented in such mental states as " I wish," "I will" and "I will not, ' which latter is many times synonymous with " I can not "

In order that feeling and desire may become motor impulses, they must be accompanied by a knowledge of the attainability of the object desired, otherwise a utile or even no effort is made to attain the object desired We thus observe the difference between "I wish" and "I will" and note that faith is one of the principal attributes of a strong will The inhibitive spect of the will which enables its possessor to say no is largely a matter of education Uncivilized man knows no master, save want, and when opportunity or indulgence offers, gives full reign to his unhalowed passions The tendency of civilization is to teach the control of the passions through the limitations of environment Man thus learns to inhibit his desires and hold in check his feelings through the inhibitory action of his will He is thereby enabled to contain himself within the bounds of decorum and decency It is by will power that man is an abstemious animal and when given over to indulgence he is simply evidencing the atavistic principle which so often crops out during the evolutionary process Civilization teaches man to "wish" and to "wait" for many things in this life, upheld by the hope of their fulfillment in some future existence, if not in this, and also that by restraining his passions and appetite he is serving his own best good

Continued indulgence in the use of narcotics finally creates an appetite Like a bad debtor, they promise much and pay little The system continually cries out for relief that comes not This irresistible craving is intensified by moral or physical restraint and the habitue is urged on by his vitiated appetite to greater and greater indulgence when opportunity offers No feat is considered too dangerous to be attempted to secure the coveted dram, no human tie too sacred to prevent the fulfillment of his unhallowed desire, even hope of future salvation is freely given up for the cup that cheereth but to damn The intensity of the passion for narcotics when once the habit has taken hold upon its victim, points only too plainly to something essentially different from a mere physical appetite Hunger for food, even unto starvation, shows no comparison in its suffering to the agony of the alcoholic inebriate or the opium fiend when deprived of his wanted potion Everything points to a diseased mental state beyond the power of any drug to reach it as an *antidote* While drugs play an important role as alteratives and tonics in the treatment of inebriety yet there is not a "cure" in existence, that has any efficacy, that does not base its permanency upon the "suggestive" methods employed in effecting the cure While it is true that some depend almost entirely upon "drug suggestion" yet the cures that promise most in permanency of results have incorporated in them a system of psycho-physics, using the term medically, that is successful in proportion as it is scientific and comprehensive

Inebriety, in all its forms, is beyond question a neurosis and permanency of cure depends upon establishing an absolutely altered mental state, together with the maintenance of a healthy environment until such time as the individual has fully regained possession of his will, and developed sufficient moral stamina to withstand the temptations of the open saloon and social life

100 State Street

FEIGNED INSANITY, REPORT OF THREE CASES

Read in the Section on Neurology and Medical Jurisprudence, at the Forty seventh Annual Meeting of the American Medical Association, at Atlanta Ga May 5 8 1896

BY WILLIAM FRANCIS DREWRY, M D
FIRST ASSISTANT PHYSICIAN CENTRAL STATE HOSPITAL ETC
PETERSBURG VA

The simulation of insanity is not an innovation peculiar to modern day schemers, though it is now frequently resorted to by designing criminals

In the sacred writings is recorded that the Shepherd King of Israel "changed his behavior and feigned himself mad and scrabbled on the doors of the gate, and let his spittle fall down upon his beard" because he was "sore afraid of the king of Gath "

In order to escape the Trojan war, Ulysses feigned insanity by plowing the sea shore and sowing salt instead of corn And Lucius Junius Brutus, it is said, played the imbecile for a purpose

To detect simulation and to establish the requisite proof of it, have at all times been matters of more or less difficulty Casper met with many cases of the sort and appreciated the difficulties which they presented Says Hammond "No one, no matter how skillful an alienist he may be, is beyond the point of being imposed upon for a short time by persons assuming to have certain forms of mental derangement" Snell remarks that if a simulator preserves a complete passiveness and an obstinate silence, it is not impossible that insanity may be so perfectly simulated that detection may not be accomplished Connolly Norman regards the question of simulation of insanity as " one of the most difficult with which alienists have to deal, one requiring much experience, acumen and sagacity, if a satisfactory decision is to be arrived at"

In his work on "Sanity and Insanity," Mercier says "There is no form of insanity that may not be simulated by a case of drunkenness, and when it is not known, from other sources of information, that these manifestations are due to drink, no expert in the world, however skillful, could distinguish between the insanity that is due to alcoholic poisoning, and the insanity that is due to other causes"

Tardieu and others think, however, that nothing is more difficult to counterfeit than mental disease and that the attempt to deceive may be easily discovered by a careful observer Conolly asserts that he can "hardly imagine a case which would be proof against an efficient system of observation"

When we remember that, besides the fact that scores of criminals resort to the insanity dodge to escape merited punishment, the truly insane sometimes simulate insanity that simulation itself may be an indication of mental alienation, and that occasionally there is a tendency of feigned insanity after long duration to become real insanity, the question of accurate diagnosis may not always be unattended with uncertainty and embarrassment To an experienced alienist there will of course seldom be any great difficulty in arriving at a correct conclusion, but to one with more or less limited knowledge of the various manifestations of mental diseases a clever imposter, with the faculty of imitation well developed, would appear somewhat in the nature of a psychic problem

At all events, before giving a positive answer to so delicate and important a question as whether one is insane and therefore entitled to all possible humane consideration, or sane, and consequently responsible for his illegal acts, a physician should study methodically and scientifically the suspected case, keeping his conscience pure and undefiled under all circumstances "His opinion," says an eminent authority, "should be founded upon the conception of pure knowledge, based upon observation and induction"

The question of disease—that and nothing more—is the one for the physician to determine Is the person whose legal or testamentary responsibility is in doubt, *insane*—is his mind affected by *disease?* That is the problem the solution of which devolves upon the physician Says Bucknill "The element of disease in abnormal conditions of mind is the touchstone of irresponsibility and the detection of its existence or non-existence is the peculiar and oftentimes the difficult task of the psychologist"

So, view the matter in any way you will, it can be only a question of diagnosis

Case 1—In February, 1895, Isaiah P was indicted on the charge of house-breaking and larceny While in jail awaiting his trial in the hustings court of a Virginia city he suddenly began acting so strangely that doubt was entertained regarding his mental condition Upon being arraigned in court his behavior was so utterly at variance with that of an ordinary sane man, he was remanded to jail and the trial of his case postponed, so that his mental condition might be investigated

The writer was appointed by the judge to ascertain whether or not the prisoner was insane Whereupon I visited him several times, dealt with him not in the rôle of a secret detective, but in that of an impartial physician, and as such proceeded systematically to inform myself as fully as possible of his history and symptoms

History and heredity—Isaiah was born in 1857, of negro parentage There was nothing of special interest connected with his early life From childhood he was a bad, indolent fellow Only two of his family were ever afflicted with any form of neurosis or of psychosis His mother at 65, was sent to an asylum in a state of senile dementia A younger sister died of phthisis pulmonalis, complicated with melancholia, while in a hospital

During a spree some ten years ago (1886 I think), Isaiah received a blow on the right side of his head which produced a depressed fracture but under careful surgical treatment he made a complete recovery, the only visible result remaining being a slight depression in the cranium On more than one occasion he was suspected of larceny, and finally, in 1888, was convicted and sentenced to five years in the State penitentiary

It was claimed by his family that he had had, since the blow on the head, several epileptic fits and been at times "curious in his ways" But in the absence of corroborative evidence these statements were accepted with a degree of reserve

Appearance and symptoms—A careful physical examination revealed nothing of special pathologic import His bodily condition was about normal

He came into my presence with an air of exaggerated excitement, moved about restlessly, took no notice of his surroundings, looked wild and uneasy talked incessantly and foolishly The almost exclusive subject of his foolish, incoherent gibberish was "locusts" He talked about locusts most of the time, but when questioned he gave answers foreign to the subject of his apparent or assumed delusion, saying he did not understand what I meant All questions were answered very slowly and hesitatingly When I told him my business his incoherence and restlessness became intensified When unobserved he became quiet and composed

Odd sensations in his head were frequently complained of He would put his hand to his head and say something was "scrambling about in here"

Memory and intelligence, to all appearances, were absolutely lost Apparently he recalled nothing that had ever happened, nor did he remember any person or place he had ever seen He could not or would not distinguish one piece of money from another, nor tell a man from a woman

To every question he gave a negative or an absurd reply For instance

Question Where were you born? Ans Caught ninety-nine locusts to day

Ques How do you feel to-day? Ans Eat locusts with butter

Ques Let me see your tongue Ans Hold up his foot

Ques Did you sleep well last night? Ans Tell him all right Here they come

Ques Tell me about the locusts Ans Had bread and shucks for dinner

Ques But what of the locusts? Ans I don't understand you

Ques How long has your mind been affected this way? Ans Some say 49 years, I say 100

Ques Have you heard from home lately? Ans Fell in river last night The locusts are [illegible] down the mountains Let them roll

He slept well several hours every night and frequently in day time after he had been [illegible] and [illegible] from constant exertion and excitement

I took occasion to remark in an undertone to the jailor, that if the patient were to sing, become noisy at night destructive to clothing, filthy in his habits, devoid of the sense of pain, my belief in his insanity would be confirmed A few days later Isaiah had become so noisy and filthy at night that he had to be isolated He had tried to be wakeful, but, negro-like, he soon fell asleep His clothes were torn, shoes thrown away, coat reversed, etc I thrust a needle into his flesh at various points, without making any perceptible impression Said he did not feel any pain at all A few minutes later, when a needle was suddenly stuck into his back, he forgot to be insensible to pain and consequently jumped some distance

My notes show many and various evidences of Isaiah's clumsy effort to "play crazy," but the above is quite sufficient to prove beyond any doubt, *simulation* I had no trouble in detecting the fraud

For two months, in fact, until the day he was taken to the penitentiary to serve out a twenty-three years' sentence, he continued his efforts to deceive Finally, however, he acknowledged the attempted fraud

In my statement to the court and jury I gave, in substance, the following as the grounds of my opinion

1 There was no prodromal stage of indisposition, malaise or depression preceding the sudden outbreak The "attack" occurred in the midst of normal health He had few symptoms of any form of insanity that might begin somewhat suddenly, viz transitory mania, epileptic mania, confusional insanity, acute hallucinatory insanity, alcoholic mania, none of which it is possible to counterfeit Then, the fixedness of the form of delusion he tried to imitate would exclude any of the above types of insanity

2 Sudden development of a fixed delusion regarding one particular subject is not consistent with the clinical history of any known form of insanity, for paranoia, *monomania* or delusional insanity, is of slow and gradual development and unattended with any special excitement, loss of intelligence, etc

3 If he were trying to appear a paranoiac or monomaniac, he overlooked many essential points, for instance, when questioned regarding his delusion, he invariably gave an answer entirely foreign to the subject, and the peculiarity of expression which so strongly marks that class of cases, was entirely wanting and, furthermore, there was no excitement or irritability of temper when contradicted

4 Loss of memory, reason and intelligence would occur in dementia, but the quickness with which he carried out my suggestions regarding the "lacking symptoms" of insanity, to say nothing about his appearance and general shrewdness, would preclude any suspicion of mental decay

5 Contrary to what is observed in acute mania and other forms of insanity, there was no sign of insomnia The more intense his restlessness, the more profound the sleep which followed

6 The hesitancy, extravagance and silliness with which he replied to simple questions, the absurd, disordered ideas which flowed slowly and thoughtfully would not be exhibited in the really insane, whose ideas form and flow rapidly, disconnectedly and are not devoid of sense

7 There were no physical symptoms upon which to base a diagnosis of either functional or organic disease of the brain The injury to the head had left no perceptible ill result, motor, sensory or mental

8 The insanity of his mother being a psychosis of old age, could have but little effect, if any, upon the offspring of her early life But the fact that she was insane and that she had an insane and phthisical child might be considered, in connection with the possible effects of the blow on the head, sufficient grounds upon which a neurotic diathesis or nervous instability might be based It is possible that in this case the head injury might have caused some moral deficiency

9 The order of development and the assumed symptoms failed to conform to the complete clinical picture of any recognized type of mental disease

10 The motive for feigning was not over-looked, though that was of secondary importance when compared with the history and symptoms of the case

Case 2 —Another instance of a criminal trying to escape the stern edict of the law by pretending to be insane, has lately come under my personal observation In this case, however, the ultimate purpose of the malingerer was accomplished

Isaac H , a negro youth, had served a few months of an eighteen year sentence in the State prison, for murder He assumed the rôle of a madman, and by taking advantage of the lax and crude method of adjudging one insane in Virginia, he succeeded in gaining admission to the insane asylum where no special arrangements are provided for the custody of insane criminals Every possible precaution was exercised to prevent his escape, yet Isaac, after a short sojourn, very ingeniously gained his liberty and has never since been heard of We had diagnosed the case correctly and were contemplating returning the prisoner to his legitimate abode I have not time here to make an analysis of the case Suffice it to say, he so far over-acted the part, and behaved so differently from any other case of acute mania—the form of insanity he was trying to counterfeit—the deception was too flagrant

The history of the case, the clumsy, over-acted symptoms, the motive, were all carefully studied, and by a process of elimination no type of insanity was left to fit his case In the words of the distinguished Dr Chapin, of Philadelphia ' The method of arriving at a conclusion is, bring together all the features in the history and manifestations of the case and then decide whether the case corresponds to a type of insanity, which in all of its features could not be simulated except by a trained alienist In this way a mistake will rarely be made "

Case 3 —Some years ago there was admitted into the Central Hospital a young colored girl, of intelligence above the average of her race, and with a physical formation well-nigh perfect Her case had been diagnosed "epileptic insanity "

It was some time before I had an opportunity of seeing her "in a fit" From the post epileptic condition I had serious doubt about the genuineness of the epilepsy Eventually I saw her repeatedly in her "terrible attacks," as her family had designated the seizures

She would cry out suddenly, then fall, snap her jaws together, make a noise like the bark of a dog, foam at the mouth and act most maniacally, etc Then she would pass into a convulsive state, jerk violently, tear off all her clothes, assume the opisthotonos position, grind her teeth, strike and snap at everything in reach, and finally pass into a quiet sleep These violent attacks would continue sometimes for an hour or two, after which the patient would become quiet and composed, her only complaint being that she felt sore Said she knew nothing of the attacks, when they came on or how they affected her, but expressed great mortification on account of her affliction

I noticed that the fall was rather guarded, that she never bit her tongue or hurt herself in any way, that the sphincters were never relaxed, that the pupils were in every way normal, the iris not insensible to light It was evident that sensory perception existed She became bathed in hot perspiration, and seemed to be well nigh exhausted

The assumed tonic and clonic convulsions were by no means like those seen in real epilepsy The post-epileptic condition she made no attempt to imitate

The girl was carefully nursed for some time, but after watching her curious maneuvers a few times, I told her that she was feigning and that the next attack she had I should put her in a room and pay no attention to her whatever My threat was promptly carried into execution, and the effect was all that could have been desired

She was soon sent home, got married, though has never had any children, and has ever since remained free from that 'epileptic insanity" which she palmed off so successfully on some of her friends for the sole purpose, as far as I could discern, of arousing sympathy There was, however, doubtless some hysteria in her case

That there is no established rule or test by which feigned insanity may be detected, but that each case must be decided upon according to the history and symptoms presented, can not be well denied Alienists everywhere, will bear me out in these assertions The individual whose sanity or insanity is being questioned should constitute the chief object of the investigation

Whenever there is doubt about the mental condition of one charged with crime, it would be well, for the court to select a committee of competent alienists to investigate the case and report in writing the result of their examinations and deliberations This need not preclude a cross-examination

In Russia and elsewhere methods similar to this prevail In some of the countries there is, I believe, a regular court physician who decides all doubtful medical cases It has been advocated in some quarters of this country that there be appointed State experts in insanity to act in all cases where an element of uncertainty exists

But the best plan, probably, would be to transfer the suspect to an insane asylum and keep him there, under proper safe-guard, for a specified time, in order that the attending physicians may determine the question of real or counterfeited insanity

For the reason that the position often taken by lawyers is so entirely at variance with the true conception of the disease—insanity—that medical witnesses, who have no special knowledge of insanity, are often called upon to give expert testimony, that physicians are sometimes utilized by shrewd counsel for partisan or for sinister purposes, that juries composed entirely of laymen are not competent to try a case which involves a question of mental alienation—brain disease—and finally, chiefly that the ends of justice and mercy are sometimes thwarted, our system of medical jurisprudence of insanity is in need of revision

---

The increase in the membership during the month of September was very satisfactory Let the good work go on'

THE ACTION OF STRYCHNIN IN PULMONARY CONSUMPTION IN RELATION TO THE NEUROTIC ORIGIN OF THIS DISEASE

Read in the Section on Neurology and Medical Jurisprudence at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga May 5-8 1896

BY THOMAS J MAYS, A M, M D

PROFESSOR OF DISEASES OF THE CHEST IN THE PHILADELPHIA POLYCLINIC AND VISITING PHYSICIAN TO THE RUSH HOSPITAL FOR CONSUMPTION IN PHILADELPHIA

Freedom of thought is the foundation of all progress, and while this law develops a diversity of opinion in practical therapeutics so great as to give rise to the belief that no two physicians treat the same disease in the same way, it is nevertheless true that in the struggle to relieve and cure disease we consciously or unconsciously seek and follow methods which finally lead to adoption of the same principles if not of the same details of treatment This unanimity in practice is sometimes reached through certain etiologic and pathologic convictions which we hold of disease, or, as is more often the case, we are driven to it by the power which comes from witnessing the successful effects of well directed medication either in the hands of others or our own, and in spite of any theory we may possess in regard to the origin or mechanism of disease

For a number of years I have said and written much in favor of the neurotic origin of pulmonary consumption, and while this theory may not be perfect in all its details, I believe that it gives us a more rational explanation of the causes and nature of this disease than any other Not only do I feel convinced of this, but my experience assures me that the therapeutic measures which are directly addressed to the nervous system are the most effective in the relief and cure of this disease Led by these considerations I have employed a number of neurotic agents in the treatment of this disease, the principal one is strychnin, to which I shall now devote a few remarks

Of all the drugs in the materia medica there is none that compares favorably with the action of strychnin in the treatment of pulmonary consumption As is well known this agent has an elective affinity for the whole nervous system, but over and above this it possesses a special influence on the nerves which preside over the function of respiration Its action is reputed to be wholly devoted to the motor nervous system, but there is reason for believing that it also affects the peripheral sensory nerves In small doses it stimulates, in medium doses it tetanizes, and in large doses it paralyzes the nervous system The dose is a relative or a movable quantity however, for that which produces tetanus or paralysis at one time may act as a stimulus at another

How, then, does strychnin act in pulmonary consumption? It is taken for granted that the lung disease is merely a superficial manifestation of disorder of the pulmonary nerve supply Therefore the strychnin primarily raises the tone of the nervous system as a whole, and of the respiratory nerves in particular In this way it not only increases the resistance of the lung to disease, but it aids digestion assimilation and blood-building Let us say that the tone of the nervous system is depressed By employing strychnin we can do this but *must* be *careful to* avoid the danger point, yet at the same time this point must be approached as closely as is consistent with the safety of the patient The best way to bring about this object is to begin with a moderately small dose of the drug, 1-30 grain four times a day, give this for one week, then increase it to 1-24 grain for another week, during the next give 1-20 grain, the following week raise the dose to about 1-16 grain, and so on, making a slight increase every week until you observe nervousness, restlessness or twitching of the muscles—the signs of the beginning of strychnin intoxication In most cases these symptoms do not develop until 1-12 or ⅛ grain or even a larger dose is reached It must be understood that the drug is to be given in these doses four or even five times a day The object is to impress the nervous system with the full stimulant effect of this drug The sooner this end is attained the better will it be for the patient For this reason you begin with small doses and work upward as rapidly as you can with safety After the desired point has been reached the question arises whether it is better to continue the largest dose or to resume the original I think it best not to vary from this line during the remainder of the treatment, for you do not wish to lose what has been accomplished Keep the strychnin treatment up to the highest level of safety, but shun the point where its stimulus extends into the region of tetanus and of paralysis It is best, however, to reduce the dose somewhat at this point If, for example, it is found that ⅛ grain is a maximum dose reduce to 1-16 grain, gradually increase the dose again until ⅛ grain is reached, and then return to 1-16 or 1-12 grain After you have increased and decreased the dose several times you will probably find that ⅛ grain no longer produces any dangerous symptoms, and that you now can give as much as 1-6 grain When administered in this way the drug may be given for an indefinite period to the majority of phthisical patients

The remedial effects of the drug show themselves in various ways The nervousness, sleeplessness and pain in the chest will be ameliorated, and perhaps entirely disappear, the cough, expectoration and dyspnea will diminish, vomiting will abate, the appetite improves, the patient gains in flesh and color, the weak and rapid acting of the heart will become slower and stronger the red corpuscles increase in number, and the patient becomes more hopeful and brighter

Of all the drugs in our possession strychnin makes the most profound impression on the nervous system, and in my opinion yields a larger measure of benefit in the treatment of pulmonary consumption than can be derived from any other single agent In connection with it I employ well regulated rest, good food, quinin, phenacetin, hypophosphites, electricity, cod liver oil, etc

I will not weary you by relating any examples from my experience in confirmation of what I have said,[1] but will quote in part a "case of phthisis apparently cured" which was reported by Dr William Pepper in the December (1895) number of *The University Medical Magazine* Female, aged 21, with a decided phthisical family history, began to emaciate rapidly in March, 1893 In less than a month she was bedridden and weighed 100 pounds She had high fever night sweats, anorexia, vomiting, copious expectoration and all the physical signs of pulmonary disintegration She received an egg albumin diet and the medicinal treatment consisted of 1-100 grain of strychnin nitrate with 1-1000 grain of atropin sulphate every two hours hypodermatically, and 1-50 grain of strychnin nitrate with 1-12 grain of the double chlorid of gold and sodium and ½ grain of a vegetable digestive every two hours by the mouth After a few days the amount of gold and sodium was increased to ⅛ grain every two hours At first she showed signs of strychnin intoxication, and the amount was reduced, but she soon resumed the original dose, and after the first two weeks bore the drug well, although always just inside the border line of its toxic action During April she improved decidedly, and during May the improvement was also very rapid By the latter part of this month she weighed 125 pounds The abnormal physical signs and the tubercle bacilli disappeared and in September she weighed 132 pounds, and was in perfect health In August, 1895, she had a slight attack of pneumonia, after which all the symptoms she had two years previously, recurred, and her weight fell to 114 pounds She was placed on her former treatment, and made a rapid recovery On November 1 she again weighed 124 pounds, her cough and expectoration had almost disappeared No tubercle bacilli have been found since the previous October

Dr Pepper, in summing up the case says, that among its noteworthy points are the absence from the treatment of all cough medication and antiseptics, and the large doses of strychnin and the double chlorid of gold and sodium with which the system was kept literally saturated

There can be no doubt that this was an apparently hopeless case of phthisis from its very outset, and great credit attaches to the distinguished prescriber for guiding it to such a successful termination The question arises as to which of the agents played the most prominent rôle in bringing about this issue From my own experience with the drugs which were employed I believe that the strychnin is chiefly responsible for this, although in forming a correct estimate we must not lose sight of the value of the nutritious food and the physical rest

When we take into consideration that insanity, idiocy, hysteria, chorea, epilepsy, asthma and all forms of nervous disorder are prone to develop into pulmonary phthisis, that the former diseases are frequently converted into the latter through heredity, that all poisons like those of alcohol, syphilis, lead, mercury, influenza, whooping cough, etc, have the power of engendering nervous disease and pulmonary consumption, and as a matter of fact the former are often followed by the latter disease, and that the markedly beneficial action of strychnin in this disease comes exclusively through the nervous system, it does not require a very great stretch of the imagination to perceive that the neurotic element plays a leading part in the etiology of pulmonary consumption

---

Perchlorid of Iron in Treatment of Ingrowing Nail—Reghi's method is being extensively quoted, as he has been very successful with it After soaking the foot until the scab is loosened and the pus washed off, a piece of cotton dipped in a 50 per cent solution of perchlorid of iron is inserted in the ungueo phalangeal groove, and the toe lightly wrapped up This is repeated twice a day, the blackish scab that forms removed each time The patient remains in bed a couple of days, and the cure is complete in twenty, although a small piece of cotton should be worn between the nail and the flesh for some time —*Bulletin Méd* , No 58

FUNCTIONAL DYSPEPSIA OF CHILDREN WITH ILLUSTRATIVE CASES

Read in the Section on Diseases of Children at the Forty seventh
Annual Meeting of the American Medical Association
held at Atlanta Ga May 5 8 1896

BY J M G CARTER, M D , Sc D , Ph D

Professor of Preventive and Clinical Medicine in the College of Physicians and Surgeons of Chicago Fellow of the American Academy of Medicine etc

WAUKEGAN ILL

The term *dyspepsia* is so frequently used by writers as a synonym for indigestion that one needs to explain the meaning he attaches to the word In this paper it is to be understood as referring to the condition which permits or encourages acute attacks of deranged digestion or unnatural distress in the stomach or bowels from the presence or absence of normal food or its products The acute attacks of interference with digestion are here termed indigestion Frequent attacks of indigestion may occur in the course of a case of dyspepsia

Functional dyspepsia includes all cases which are not due to some organic lesion of the stomach Many cases of gastritis in children are sequelæ of indigestion and must be carefully differentiated from functional dyspepsia But cases resulting from undeveloped stomachs properly belong in this class From these limitations and explanations it may be seen that we include under the term functional dyspepsia cases which result from some congenital imperfection in structure, from improper food whether of quantity or quality, from variations of temperature especially increased heat, from the presence of bacteria or their products, from reflexes caused by diseases in other parts of the body, and from weakness following or accompanying general illness

Case 1 —I have lately had under my care a baby born before the termination of the eighth utero gestation month It was small and though perfect in limb and feature, had little vitality Its digestive powers were so feeble that its mother's milk caused it great distress The mother's milk ceased in a few days A wet nurse was secured but was soon dismissed because relief was not obtained and because the baby seemed to dislike the milk Cow's milk, diluted, raw or sterilized or condensed, was borne but a short time without distress Malted milk food (Horlick's) agreed for a short time, and then a return was made to cow's milk These experiments occupied ten weeks The milk was then predigested, with worse results apparently than had been experienced before The bowels alternated between constipation and diarrhea Vomiting was occasional, usually the dejecta consisted of the food unchanged Fermentation and gaseous eructations were frequent. The child continued to grow and gain flesh There was no doubt in my mind that the cause of the disturbance in this case was imperfect or under development of the stomach

Such cases may persist through childhood and even to adult life When they do it is difficult to differentiate them from another class of cases, which result from cicatrices following ulcers of the stomach

Case 2 —I was called to see a baby seven or eight months old, at the breast It was emaciated, yet nursed feebly Examination of the mother's milk showed it to be poor in quality but abundant in quantity The baby suffered pain from gaseous distension of stomach and bowels Vomiting was frequent, and occasionally diarrhea Treatment made no special impression Then the infant was given cow's milk but with no beneficial result, rather an increase of the dyspeptic symptoms Other changes were made without relief until condensed milk (Swiss brand) was given Very soon after this change the digestive derangement subsided and the little patient began to gain flesh The recovery was complete This case was undoubtedly one due to dietetic disturbance

Case 3 —The influence of heat is illustrated by the following case I was called in July to see a baby which was suffering with diarrhea The patient vomited occasionally, suffered some distress in the stomach and bowels, took its mother's milk ravenously, diarrhea lienteric, except when charcoal, lime water or pepsin were given, then the discharges were better for a time The child was ten months old The weather was very warm At first directions were given to remove nearly all clothing, bathe the patient frequently and keep it cool The treatment was followed by immediate improvement The weather became warmer, the patient worse The use of cold water and ice relieved the symptoms The patient's temperature was not increased There were no evidences of enteritis or colitis On cool, cloudy days the case was better, on warm days worse A change to cow's milk was followed by negative results, no increase or diminution in symptoms The patient recovered when cool weather came

Case 4 —That the presence of bacteria may cause dyspepsia in an infant is well illustrated by the following Baby F was a year old, a bottle baby It had attacks of stomach derangement every few days or weeks, especially during the summer At such times it had colicky pains, distension of stomach and bowels, vomiting of coagulated milk, with similar coagula passing from the bowels, causing diarrhea No fever When I was called the condition was such as just described, somewhat aggravated by the warm weather Everything about the child was dirty, an innumerable host of flies trying to clean things up The bottle nipple was not clean, having many specks of milk coagula and fermented flakes upon it The bottle was in the same unhygienic condition Similar specks were found in the baby's mouth Although a microscopic examination was not made, I was satisfied that the case was one of functional dyspepsia due to the bacteria and their products engendered in what was evidently a favorable culture medium The treatment, which consisted in cleaning up the field for operation and the use of antiseptics, confirmed the diagnosis by producing a cure

Case 5 —Cases of functional dyspepsia due to some neurosis are rare in young children, but the following I think well illustrates a case due to reflex influence induced by disease in some other part of the body I was called to see a boy 5 years old who had been suffering with poor appetite and deranged digestion for some months Gaseous eructations were frequent, but the stomach was not permanently dilated nor very frequently distended by gas Food of almost any variety and kind, whether nitrogenous or non nitrogenous, caused more or less distress Soon pyrosis and other symptoms made eating dreaded A few weeks after the beginning he showed signs of failure of nutrition, began to be anemic, lose flesh and grow weak The bowels were regular No tenderness of the stomach was manifested and the temperature was not above normal About two months from the first indications of disturbance I was called because constipation had become troublesome and a tumor was discovered in the lower part of the bowel Examination revealed no organic disease of the stomach, but did reveal a sarcoma of considerable size in the pelvic cavity, chiefly to the right of the median line The tumor, about 4 inches in diameter, pressed upon the rectum and interfered with the normal evacuations of the bowel Perhaps eventually the fermentation and ptomains occurring in the bowels caused by retained feces were prominent factors of the gastric as well as intestinal disturbances The case passed rapidly to a fatal termination without further gastric derangements than those due to reflex influences and the poisoning caused by fecal ptomains

Case 6 —The last case I desire to mention was one who had been prostrated for several weeks with typhoid fever He was 8 years old and had been greatly weakened by the long sickness When the milk diet was no further insisted upon and a gradual change was made to other food, gastric disturbances in the way of eructations, distress, distension and heartburn were frequent These continued for three weeks They were due to the anemic and atonic condition of the stomach and should certainly be considered functional disturbances Dietetic care and recovery of strength and health removed all dyspeptic symptoms, so that after three weeks and since there has been no evidence of gastric trouble

Other cases of anemia and atonic conditions may be accompanied by functional dyspepsia, just as in adults

This brief presentation of cases will help to impress the writer's views of etiology and treatment of functional dyspepsia By far the greater number of cases are due to improper food, the improper administration of food or to reduced vitality An extended experience with the use of hydrochloric acid and pepsin will convince one that the relative number of cases cured by these remedies is small in fact, the number benefited will be disappointing Still we can not rely exclusively upon dietetic and tonic treatment An attempt to render the alimentary [illegible] aseptic i paramount The following are the chief indications to be met in this condition 1 Correct the food both as to quantity and quality 2 Try to render the stomach and intestines aseptic 3 Assist nature in her effort to restore the natural functions and tone up the system

1 Too frequently the undeveloped state of the salivary glands in the first few months of infancy is forgotten and food, such as rice water and cereal preparations, is given which can not be digested in the stomach and in many cases at least is not completely digested in the intestines A similar result may obtain if given in too large quantities later in life Under such circumstances the undigested food becomes a nidus for the growth of bacteria, fermentations result, irritating gases and bacterial products may cause diarrhea and at times constipation A too abundant proteid diet of eggs and meat may in a similar manner and for the same cause result in putrefactive decompositions and the gases formed likewise produce constipation or diarrhea, even in older children

2 The rational treatment in these cases is, of course, antiseptics An effort should be made to correct or remove the cause and give antiseptics Antiseptics can not be given in sufficient amounts to overcome the condition unless an irritating diet be corrected, especially is this true in nursing and bottle babies It is true also in older children Salicylate of bismuth, salol, carbolic acid, charcoal and other antiseptics used in these conditions have given me excellent results I have treated diarrheas due to indigestion in the same way with like results In functional dyspepsia, however, a habit of indigestion may be established, as it were, and a tendency to certain bacterial growths may become persistent Here it is necessary to persevere in an antiseptic course of treatment I have lately treated bacterial diarrhea of a very aggravated type, in patients old enough to be ng a mixed diet, by the administration of a milk t and salol without other medication and with the st satisfactory results Salol may be given in doses one to two grains every two or three hours until provement occurs Infants under one year yield ry readily to salicylate of bismuth Where from osyncrasy or other cause the salicylate is not well borne, salol in one-half grain doses will frequently be all that is needed In many cases minute doses of calomel act as an antiseptic and afford gratifying relief Cases of summer complaint preceded or accompanied by functional dyspepsia frequently yield quickly to the antiseptic treatment The same is true of those dyspeptic cases following prostrating fevers, neuroses and other forms of exhaustion in which there is fermentation or putrefaction of food due to delayed or weak digestion and the formation of irritating gases The dilatation of the stomach which so frequently accompanies functional dyspepsia in children is nearly always due to gaseous distention and is temporary The removal or diminution of the gas is a step toward a cure Where much distention exists and antiseptic practice does not afford ready relief, the stomach-tube or a soft catheter may be introduced through the mouth or nose and the gas allowed to escape The general douching of the stomach seems to me to be less valuable in children than in adults, but sometimes it is useful to remove offending matters The douche is sometimes of value also in atonic cases where the gastric walls are relaxed by over distention or a weakened condition of the general system, anemia, etc

3 Finally it is necessary in many instances to give hydrochloric acid, pepsin, lactopeptin, peptenzyme, papoid, diastase and similar preparations to help correct the deranged secretions and assist in digesting the food In addition to the administration of these internal remedies which act chemically or by catalysis, stomachics, the aromatic sulphuric acid, nitric or the nitro muriatic acid and other preparations to stimulate the secretions may be needed An alcohol sponge bath twice a day followed by inunction with cocoanut or olive oil to which quinin may be added in suitable cases, frequently aids materially in restoring the patient to health and vigor The use of malt preparations and other tonics is frequently demanded The anemia, neurasthenic or other conditions of depressed vitality will guide in their administration

THE TREATMENT OF CHRONIC INFLAMMATION OF THE BLADDER, WITH REPORTS OF TWO CASES OF CONGENITAL DIVERTICULA

Read before the Colorado State Medical Society, June, 1896

BY LEONARD FREEMAN, B S , M D
PROFESSOR OF PRINCIPLES OF SURGERY AND SURGICAL PATHOLOGY GROSS MEDICAL COLLEGE, SURGEON TO THE COUNTY HOSPITAL AND ST ANTHONY'S HOSPITAL,
DENVER COLO

Chronic inflammation of the bladder is practically always due to microörganisms, the one most often encountered being the bacillus coli communis, which exists normally in such abundance in the intestinal canal The gonococcus, the tubercle bacillus, the typhoid bacillus, the various pyogenic bacteria, etc , are also frequently found It should never be forgotten that it is not a calculus, an enlarged prostate a tumor, or a quantity of residual urine which is the direct cause of an inflammation, but the bacteria which have in some manner gained entrance to the bladder in presence of these conditions Even a cancer does not produce inflammatory symptoms until infection has taken place I had recently under my care an old gentleman with vesical carcinoma, whose urine remained free from pus for a considerable time after the growth began It is possible for germs to enter the bladder through the kidneys, the urethra, and even through the blood, but in most cases catheterization is responsible for simple infection A vesical calculus may exist for years without a sign of cystitis, provided no instrument has been introduced into the bladder I have seen a man with an enlarged prostate whose bladder had been dilated, almost to the umbilicus, with residual urine for over two years, and yet the urine when removed was as clear as spring water

From a therapeutic standpoint, chronic inflammations may conveniently be grouped under three heads 1, inflammation in connection with the presence of a foreign substance—calculus, tumor, piece of catheter, etc , 2, inflammation in connection with the presence of residual urine, 3, inflammation due to specific infection, such as gonorrhea, tuberculosis, syphilis, etc Under the last heading may be placed inflammations due to certain microörganisms other than those of the diseases mentioned

The first two groups are closely allied It is not so much because a foreign substance exists, or because it injures the mucous membrane, that inflammation occurs, but because the bladder is unable to clear itself sufficiently of objectionable ingredients of the urine, which remain collected about the substance. In other words, it is to the residual urine that the trouble is due. Nevertheless, the divisions given above are retained for the sake of convenience.

1. Inflammation in connection with foreign substances.—It is self-evident that rational treatment indicates removal of the offending substance, be it stone, tumor or other material. Simple removal is usually sufficient, provided no obstacle to complete emptying of the bladder remain, such as atony, a diverticulum, etc. I have observed a case in which a stone had existed in the bladder for nearly fifteen years, where the marked inflammatory symptoms disappeared within a few days after lithotomy had been performed.

2. Inflammation in connection with residual urine.—This is found in enlarged prostate, stricture of the urethra, paralysis and paresis of the bladder, certain diverticula, etc. In case of stricture, the enlargement of the narrowed urethra is the essential feature of treatment. The management of other forms is not so simple, and often taxes the surgeon's resources to the utmost.

General treatment.—It should be appreciated by all that general treatment is of much less importance than is usually supposed. The various balsams, resins and other compounds, so often mentioned in books and so widely advertised, often do some good, but as curative agents they are sadly deficient. They are, nevertheless, prescribed on every hand, frequently to the exclusion of local measures. Local treatment in chronic cystitis is the only reliable treatment.

We do not speak at present of "soothing the mucous membrane" by internal remedies, but of "inhibiting bacterial growth by means of antiseptics." Good may be accomplished in this way, although much less than is often imagined. Perhaps the most satisfactory drug for the purpose is salol, given every few hours in 5 grain doses.

The patient's bowels should be kept open, not only because constipation leads to congestion of the vesical veins, but because there is no more efficient method of removing poisonous substances from the system than through the bowels. The necessity of proper foods, tonics, cleanliness of the skin, etc., will suggest itself. Plenty of milk at frequent intervals does excellent service, both as a food and as a diluent of the urine.

Local treatment.—The main indications are: 1, disposal of residual urine; 2, washing out the bladder.

Residual urine.—This must be removed, no matter how small the quantity. If the urethra will easily admit a catheter of sufficient size to thoroughly drain off not only all traces of urine, but stringy pus and clots of blood which may also be present, then the regular use of a catheter will often be sufficient. When the inflammation is obstinate or severe, a soft catheter may at times be tied in and continuous drainage instituted. This method, which is not extensively used in this country, gives excellent results, even in cases of enlarged prostate. But if only a very small or specially constructed instrument can be employed, or if the patient can not be entrusted to catheterize himself, or if the channel is irritable, or if there are other reasons why the use of a catheter is unsatisfactory, then more radical procedures become necessary. At the present day the operative measures most frequently adopted are castration, resection of the vasa defferentia and suprapubic cystotomy with retention of a permanent opening. A sufficient number of cases have been reported for us to say with considerable certainty that, in general, castration furnishes the surest and safest means of combating the evil effects of an hypertrophied prostate. Some cases of inflammation, however, are so severe, and the debilitated patient so much in need of immediate relief, that suprapubic cystostomy should be done at once, and thorough drainage of the bladder secured. In all other cases castration is applicable, provided the nature and consequences of the operation are fully appreciated by the patient. Among those within the age of sexual activity there will always be some who naturally object to the removal of the testicles, no matter how strongly the operation may be indicated. For these the older operation of prostatectomy is indicated, although it should not have the preference, on account of its uncertainty and danger. For patients who, while recognizing that their term of sexual activity is past, still object to castration for various reasons, resection of the vasa deferentia may be done, although it offers at present a less certain prospect of cure than removal of the testicles.

Washing out of the bladder.—Several points should be borne in mind in this connection.

1. The bladder must not be over distended, as this may keep up a chronic inflammation which would otherwise tend to subside. There is also reason to suppose that septic material can in this way be forced into the mouths of the ureters, thus leading to kidney complications. No more than four or five ounces of fluid should be employed, and less than this is often preferable. A good-sized syringe of hard rubber, which can be easily used with one hand, is safer and better adapted to the purpose than a fountain syringe, although the latter is in general use.

2. The prostatic urethra should be irrigated as well as the bladder, especially in gonorrheal affections, as it is often the seat of inflammation which may reinfect the adjacent viscus. The catheter should be slowly inserted while the fluid is being injected until the fluid no longer appears anteriorly at the meatus, but passes through the deep urethra into the bladder, the eye of the catheter being just beyond the constrictor muscle. When practicable, it is well to leave considerable fluid in the bladder, which the patient is instructed to pass after the catheter is removed, thus irrigating the channel from behind forward. If the bladder, however, is insufficient, and the solution not a mild one, it is better to withdraw it entirely. In obstinate cases of posterior urethritis it answers an excellent purpose to occasionally inject a few drops of concentrated solution of nitrate of silver (½ to 5 per cent.) with an Ultzmann's capillary injector.

3. A single, not a double, catheter should always be used. The current from a double catheter selects a short, easy channel for itself, and passes directly from one eye of the instrument to the other without distending the folds of the mucosa and cleansing the bladder as it should.

4. When the organ is not too sensitive, the fluid should be injected with some force, so as to more effectively wash the mucosa.

5. The catheter should be soft rubber or linen, as large as can be used without undue discomfort, especially when thick pus and clots of blood are present,

secured around the waist and under the perineum by rubber bands held the ball in position The patient has been wearing this apparatus in perfect comfort for about three months, and finds that he is inconvenienced scarcely at all by his condition, while his health and energy have been completely restored

An examination of these two cases presents some interesting points 1 Congenital diverticula can exist for many years without their possessors being aware of any abnormality 2 Cystitis may not take place until infection is caused by catheterization, gonorrhea, etc 3 Cystitis in the presence of diverticula may sometimes be cured without opening the bladder, and remain so indefinitely, provided reinfection is not brought about 4 Hemorrhage from chronic cystitis may be so great as to strongly simulate hemorrhage from a tumor 5 Residual urine, without stricture of the urethra, enlargement of the prostate, or paresis of the bladder, should be suggestive of a diverticulum 6 Even in the best hands, the opening of a diverticulum may be overlooked with the cystoscope Perhaps a reason for this is that the mucosa during life is so congested and folded about the opening as to conceal it 7 In obscure vesical affections, with cystitis, it is rational to open the bladder for purposes of exploration and drainage, the preferable incision being the suprapubic, as offering the better opportunity for removal of foreign bodies, if such be present

DANGERS OF BICYCLING, WITH REPORT OF A CASE OF ACUTE DILATATION OF THE HEART

BY WILLIAM C KRAUSS, M D

PROFESSOR OF NERVOUS DISEASES MEDICAL DEPARTMENT NIAGARA UNIVERSITY BUFFALO N Y

Ever since the great popularity which has attended bicycling in this country numerous articles have appeared in the medical and lay press pointing out real and imaginary dangers liable to beset those attracted to this sport These dangers have attended both sexes, more particularly the female bicyclists, and consisted in disturbances affecting the pelvic viscera No doubt over-indulgence in this pastime can and will produce congestions and irritations of these organs, perhaps displacements and even inflammations, but such cases are comparatively rare

From the moral point of view another danger has been discovered by the Woman's Rescue League of Washington That the bicycle is nothing more or less than the devil's advance agent, and through the opportunities which it offers is causing an alarming increase of immorality among women The writer believes this to be true only in so far as it affects those women upon whom the devil already has a mortgage, and employs the wheel only as a subterfuge to foreclose the claim The wheel has been a great aid to physicians in the treatment of neurasthenic, hysteric and hypochondriac women, and the good it has done to them and the pleasures derived from it by others will more than counterbalance the harm which those unable to ride think it has and may create Pleasure and health can be derived from bicycling only so long as the laws of hygiene and common sense are heeded, and then violation will be followed by disagreeable consequences

The male sex is predisposed to that ungainly and unhuman distortion, the "camel's back," as a result of faulty posture and ambition for speed, and perhaps fame Not only is the spinal column strained and distorted, but the thoracic and abdominal viscera are subject to undue pressure, and hence to restricted movements and imperfect physiologic action No sport is a healthy one which in its performance coerces the body into an unnatural position, and the great popularity attained by rowing and base ball is partly due to the comfort and pleasure which the normal position of the body insures

Through long-continued pressure caused by long rides and faulty fitting saddles, the male genito urinary tract is liable to damage, and this should therefore be carefully guarded against The dangers which do, arise, however, from bicycling affect the beginners, and scorchers mostly, who have not learned the secret of the sport, namely, moderation

After consent is obtained from the family physician to ride, a properly geared wheel should be selected, with an easy and comfortably fitting saddle, the handle bar raised so as to give the body an erect and graceful position, and this advice constantly borne in mind, that the sport should be discontinued at the first sign of fatigue As the days go by this fatigue will grow less and less, and the rider able to take longer spins as the muscles become firmer and more accustomed to this form of exercise The whole system undergoes a certain kind of training or physical education, the heart and respiratory muscles accustoming themselves to the necessary strain just as do the extensors of the thighs and the calf muscles Just as over-indulgence results in tiredness and lameness of the leg muscles, so also are the heart and respiratory muscles affected The heart through increased work put upon it by long, rapid spins is taxed to its utmost, and when persevered in, serious damage to the heart walls or heart valves may result As Osler truthfully says "Endurance in prolonged contests is measured by the capabilities of the heart and its essence consists in being able to meet the continuous tendency to overstep the limits of dilatation "

One form of heart trouble especially is attended upon over-exertion and over-fatigue, namely, the acute dilatation of the heart walls, due to over distension of the muscle fibers The cause of this dilatation is an incomplete exhaustion of the ventricles, generally the right, during systole, and an excessive engorgement during diastole with possibly some defective nutritive change in the muscle fibers The symptoms arising from this condition are subjective and objective and are well illustrated in a case which recently came under my observation

James H C , age 37 years, height 5 feet 6 inches, weight 138 pounds, married and has eight children He had an attack of rheumatism when 12 years of age, and typhoid fever when 29 Has always been a hard working man, employed on the railroad sometimes ten to fourteen hours daily About May 1, 1896, he purchased a wheel and rode occasionally from his home to the railroad yards, perhaps a distance of half a mile On May 8, 1896, he accompanied a few friends on a spin into the country and rode four miles in twenty five minutes On dismounting he noticed a severe pain over the left side of the chest extending to the neck also that he was completely "winded" and the left side of the chest was throbbing violently After only a few minutes rest, urged by his friends he remounted the wheel and rode home, covering the distance in thirty minutes On reaching home he could scarcely breathe, was in profuse perspiration trembled all over and was obliged to go to bed Vomited during the night the following morning he found he was still in the same condition and was unable to go to work and scarcely able to be on his feet The least exertion caused his left side to 'thump' vigorously while the vessels in the neck throbbed so wildly as to make them perceptible Patient also noticed a feeling of weakness all over the body and a stiffness of the knee joints, accompanied always with great dyspnea

After remaining idle for several weeks and not obtaining very much relief, he consulted me on July 20, 1896, for "weakness and trembling," thinking that he had some nervous disorder, he stated that his sickness began on May 8, 1896, that he worked the day previous and up to that day was in his usual good health

Status Præsens —Face has an anxious, apprehensive expression, eyes are glassy and facial muscles quivering Pallor and emaciation are pronounced There is a slight tremor to the head is not painful on percussion and has never had headache

The examination of the eyes was made by Dr R H Satterlee, of Buffalo, N Y "Ophthalmoscope shows hyperopia, right eye 2 diopters, left eye 1 diopter No astigmatism could be discovered Both eyes have unsteady lateral movement Left eye does not move as freely as right eye Weakness of all eye muscles, particularly the interni Accepts no glass at first, vision later after wearing R + 50 D, L + 25 D for half an hour, 20 20 These prescribed to be worn two months constantly"

Strength of arms diminished, dynamometer test shows, right hand 60, left 40, tremulous and with increased tendon and muscular reflex action The legs likewise are weakened, also tremulous, and the reflexes are exaggerated There is no anesthesia or hyperasthesia of the face, arms or legs

The chest offers the most important symptoms, both objective and subjective The precordial area is largely increased and reverberates with every heart beat The apex point is diffused and impossible to locate On palpation a tremulous and purring sensation is experienced which is communicated to nearly the whole side of the thorax Percussion shows increased area of cardiac dullness extending to the right of the sternum, to the left of the mammillary line and below the nipple Auscultation does not reveal any valvular murmurs, although the sounds are indistinct and diffused The heart beats number 130 to 150 per minute

Urine is increased in quantity, but does not contain albumin or sugar Bowels are regular Sleep is fair but is often awakened by the heart's action During the day he is aware of much fluttering of the heart while napping

On July 27, 1896, I again had occasion to see the patient and found his heart in practically the same condition, beating 130 times per minute, and as tumultuously as on the former examination

The history of this case leaves little doubt as to the correctness of the diagnosis—acute dilatation, and the cause of such dilatation—over bicycling The distance covered and the time would be insignificant to a trained wheelman, but to one not accustomed to long rides it was quite an undertaking and was fraught with serious consequences In conversation with beginners in the sport one hears so often, "I rode eight or ten miles to-day in such a time," or "I rode a mile in such a time and have only been on the wheel a few days," and yet these riders may never have taken any kind of regular physical exercise They certainly are imprudent and should be discouraged in their ambitious tendencies until they are in condition to endure the necessary strain To the writer this seems one of the greatest dangers of bicycling and yet one of the easiest to avoid

---

THE STATISTIC EVIDENCES OF THE VALUE OF VACCINATION TO THE HUMAN RACE, PAST, PRESENT AND FUTURE

Read before the American Medical Association at the Jenner Centennial Celebration, held at Atlanta, Ga, May, 1896

BY EUGENE FOSTER, M D

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE AND STATE MEDICINE AND DEAN OF THE FACULTY OF THE MEDICAL DEPARTMENT UNIVERSITY OF GEORGIA, AUGUSTA GA

(*Continued from page 753*)

[30] Dr Kinnis, formerly Superintendent of Vaccination at Colombo, in his "Report on Smallpox as it appeared at Ceylon in 1833–4," and in an appendix relating to observation made by Dr Forbes in the epidemic of 1830, gives enumerations from which the annexed table is compiled It will be observed that the gradation of death rates marked in the last column, though far less detailed than in Mr Marson's statement, is to the same general effect And in the cases noticed by Dr Kinnis himself the difference is further developed, for he distinguished persons pretending to have been vaccinated into such as had no marks and such as had unsatisfactory marks of vaccination, and found that the *death rate of the latter was* 26$\frac{1}{3}$, *that of the former* 32 1 7 Cases of chickenpox are not included in the annexed table, and Dr Kinnis gives at length (pp 10–14) his reasons for concluding "that the febrile eruptive disease known in Ceylon by the name of chickenpox arises from an infectious matter essentially different from that which produces smallpox and modified smallpox"—Op cit Colombo, Govt Press, 1835

Occurrences and fatality of smallpox

	Number of cases	Number of deaths	Percentage of deaths
In persons decidedly not vaccinated	851	146	41 5
In persons having no marks or but unsatisfactory marks of vaccination	199	52	26 1
In persons having satisfactory marks of vaccination	187	3	1 6
In persons having marks of smallpox	4	2	

Comparison of the number of cases of smallpox which were treated in the General Hospital at Vienna during the 5 years 1851–55 inclusive as regards the *ages of patients and the number of cases which terminated fatally*

Age of patients	Vaccinated		Not vaccinated	
	Total number	Number of deaths	Total number	Number of deaths
To 10 years of age	55	8	34	15
From 11 to 20	834	16	111	25
From 21 to 30	892	43	83	23
From 31 to 40	171	7	10	5
From 41 to 50	35	1	8	3
From 51 to 60	9	1	8	
Total	1,995	76	244	71

The number of cases of variola in various forms was 2,239, namely

Who had been vaccinated	1,995
Who had not been vaccinated	244

Vaccinated as well as non vaccinated persons were seized with the smallpox, still, with this difference, that of the vaccinated cases 8$\frac{1}{3}$ per cent, but of the non vaccinated 33 3 per cent were cases of variola vera

Of the 1,995 vaccinated cases 76, and of the 244 non vaccinated cases 71, terminated fatally

[31] "Interesting and instructive are, moreover, the following figures which throw light upon the relation existing between unvaccinated, vaccinated and revaccinated persons becoming sick or dying of smallpox According to the memoranda of certain hospitals, among those who died of smallpox during the years 1870 and 1871 were

	Unvaccinated Per cent	Vaccinated Per cent	Revaccinated Per cent
In Muenster	80	13	0
In Posen	70	12	2
In 4 hospitals of Berlin	54	13	0
	70	16	4
	66	15	4
	81	14	9

In Chemnitz in 1871, among 249 dead were only seven vaccinated persons

According to Buchanan in 1881 in England, there was only one victim who had been vaccinated while there were 200 deaths among unvaccinated children from 1 to 2 years old

In Bavaria in 1882, among the smallpox cases were counted 14 6 per cent vaccinated, 5 8 per cent revaccinated, 45 5 per cent unvaccinated

In the Imperial General Hospital of Prague during ten years, from 1847 to 1856, 872 persons were treated for smallpox, of these, 819 had been successfully vaccinated, and forty three unsuccessfully or not at all With ten the vaccination or its result, could not be ascertained in a manner to be relied upon. Here must be particularly remarked that in 1847, in the aforementioned institution, not one case of smallpox is recorded

Out of the 872 patients, sixty three died, and of this number forty one were of those who were described as successfully vaccinated, twenty as vaccinated without success, and two as those concerning whose vaccination nothing certain was known

---

[30] See first report Royal Vaccination Commission, 1889, p 75

[31] U S Consul Berlin loc cit

Leaving out those concerning whose vaccination nothing could with certainty be said, it is here shown that of the successfully vaccinated the twentieth part died, of the unsuccessfully vaccinated the half, while the number of vaccinated patients was nineteen times greater than that of the non vaccinated

In the Hospital of the Brothers of Mercy at Prague, during the years 1847 to 1856 inclusive, 410 patients were treated for smallpox, of these, 370 were vaccinated, and only forty non vaccinated Of the vaccinated four died, of the non vaccinated five died

Of the vaccinated (the success or non success of the vaccination not being taken into consideration) the ninety second part died, of the non vaccinated the eighth part died, while the number of the vaccinated was nine and one fourth times greater than that of the non vaccinated

In the Elizabethan Hospital at Prague, during six years, from 1851 to 1856, 118 cases of smallpox were admitted, of these, 108 were vaccinated and ten non vaccinated Of the vaccinated two died, of the non vaccinated one died, *i e*, one fifty fourth of the vaccinated, and one tenth of the non vaccinated, the vaccinated patients being ten and four fifths times the number of the non vaccinated

In order to arrive at an idea as to the frequency of attacks of smallpox during the different periods of life, and the amount of safety secured by vaccination, we subjoin the following tables, which show the rates of mortality among the vaccinated and non vaccinated patients of the General Hospital, Vienna, during the period above mentioned

Ramsey on smallpox, Transactions New York Medical Society

Ages	Total number of cases	Vaccinated		Non vaccinated	
		Cases	Deaths	Cases	Deaths
1 to 10 years	418	234	35	184	74
11 to 20 years	2 634	2 228	83	406	83
21 to 31 years	2 671	2,329	128	342	115
31 to 40 years	406	354	21	52	24
41 and upward	84	72	4	12	4

Deaths per 100 cases at each age, as follows

	1–10	11–20	21–30	31–40	41 and upward
Among 5 217 vaccinated	14 9	3 7	5 6	5 9	5 5
Among 996 non vaccinated	40	20 4	33 6	46 2	33 3

Report of the Faculty of Medicine at Prague, submitted to Minister of the Interior November, 1856

Vaccinated and unvaccinated cases of smallpox which terminated fatally, according to the official vaccination return (21 years)

Year	Cases of vaccination	Remaining non vaccinated [3]	Smallpox			
			Cases		Deaths	
			Vaccinated	Non vaccinated	Vaccinated	Non vaccinated
1835	132,727	4 029	505	430	20	136
1836	130,194	3 319	374	215	26	64
1837	126 123	3 971	57	123	4	52
1838	133 527	3 967	101	96	15	32
1839	132,523	3 906	160	168	20	70
1840	140 895	3 585	1 138	966	89	351
1841	139,471	3 482	1,585	1,522	83	552
1842	142 970	3 180	681	703	39	208
1843	142,314	2 874	627	714	21	229

1855	156 424	2 349	389	156	8	56
Total	3 005,578	90 150	8 178	7 462	425	2 224
Average	$143\,122\frac{16}{21}$	$4{,}291\frac{19}{21}$	$389\frac{9}{21}$	$355\frac{[illegible]}{21}$	$20\frac{3}{21}$	$105\frac{19}{21}$

Remarks—One case of smallpox occurs among 36⅔ vaccinated 12⅓ non vaccinated One fatal case of smallpox occurs among 7,166⅓ vaccinated 40⅔ non vaccinated Among cases of smallpox died the nineteenth part of the vaccinated the third part of the non vaccinated

"M Bousquet,[33] in his detail of the epidemic which prevailed at Marseilles in 1825, states that the whole population was estimated at 40,000 Of these, 30,000 had been vaccinated, 2,000 had had smallpox, 8,000 had neither been vaccinated nor had smallpox Of the 30,000 vaccinated 2,000 were seized with smallpox, twenty of whom, or one for every hundred affected, died Of the 2,000 who had before had smallpox, either naturally or by inoculation, twenty were attacked, and of these four died, or one for every five who took the disease Of the 8,000 who had not been vaccinated nor had smallpox, 4,000 contracted it and 1,000 died, or one in every four By this it appears that one half of the non vaccinated, one fifteenth of the vaccinated, and one hundreth of the variolated took the disease But such was the difference in the comparative mortality of the attack in the vaccinated and the variolated, that while the variolated part of the population were cut off in the proportion of one out of every 500, the vaccinated lost only one out of every 1,500, or, in other words, of an equal number of variolated and vaccinated cases, three of the variolated died from the second attack, for every one that died who had been previously vaccinated "

In Berlin in the year 1872,[34] the mortality of the disease was 243 per 100,000 population, and the year after it was 262 Thereupon vaccination during the first year of life and revaccination at the age of 12 years was made compulsory by law, and with the effect that in the year 1875 the death rate was lowered to 36 per 100,000 inhabitants, the next year it was lowered to 31, the next to 3 and so through later years with an average annual mortality of 1 7 per 100,000 people During the year 1890 only fifty eight cases occurred in the whole German Empire, or 1 18 cases to each 1,000,000 of population

A village in Leicestershire, England, of 1,300 inhabitants was visited by the pestilence in 1872 All but two of the inhabitants were efficiently vaccinated and escaped the disease, whereas the two unvaccinated persons died of it

The late Dr J H Rauch, for many years Secretary of the State Board of Health, has shown that in the Illinois epidemic of 1881–83, the mortality rate of the vaccinated was approximately 6 per cent, and of the unvaccinated it was 49 per cent

Corbally has demonstrated that in the Sheffield, England, epidemic of 1887–88, vaccinated children were, as compared with the unvaccinated, twenty times less liable to attack from smallpox, and twenty four times less liable to die when attacked That is to say, the vaccinated children had, as compared with the unvaccinated, four hundred and eighty fold security against death from smallpox

In the Halifax, England, epidemic of 1892–93, the death rate from smallpox among vaccinated persons was 1 8 per cent, and among the unvaccinated it was nearly 41 per cent No case occurred in a vaccinated child under 5 years of age, and in the Leicester epidemic of 1893 no case occurred in a vaccinated child under 10 years of age

From the records of 5,000 cases treated in the Municipal Hospital of Philadelphia, according to W M Welch in the *New York Medical Journal*, March, 1894 it appears that the death rate in that institution in post vaccinal cases, and all in which there had been an attempt at vaccination are included, was 16 26 per cent, and the death rate in non vaccinal cases was 58 38 per cent

Seventy three per cent of the cases in unvaccinated infants under 1 year of age ended in death, and no fatal case occurred among vaccinated infants of the same age Between the ages of 1 and 7 years the mortality of post vaccinal cases was 5 7 per cent and of non vaccinal cases it was 51 48 per cent

In Chicago only seventeen cases of smallpox have occurred in the last fifteen years among the well vaccinated public school children of that city, whose average number exceeded 200,000

Dr Clendenin,[3] health officer of Cincinnati Ohio says that, in the epidemic of smallpox in that city (1868–69) 95 per cent of those who died of smallpox were among the unvaccinated He further says that no death occurred from smallpox in which there was unmistakable proof that the individual had been properly vaccinated

Dr Benj Lee of Philadelphia, Pa in his report to the Pennsylvania State Medical Society 1873, shows that the mortality from smallpox in the epidemic then just ceased was 55 9 per cent in the unvaccinated in the vaccinated with one vaccinal scar it was 15 2 per cent, while the mortality among those having five or more scars was 5 5 per cent

---

[3] I presume that ungeimpft verblieben in the third column is intended to denote (in comparison with the total births of the year) the number of infants who remain unvaccinated at the end of the legally specified time —[J S

[33] Transactions American Med Assn 18[illegible], p 2[illegible]

[34] Vital Statistics Indiana 18[illegible] p [illegible]

[3] Dr W B Davis Transactions Ohio Medical Society 18[illegible]

During 1875 the mortality among 1,866 vaccinated persons treated in the Riverside Hospital, New York City, was 375, while among the 405 patients who had never been vaccinated, 200 died

Statistical tables demonstrating the unquestionable controlling power of vaccination over smallpox might be multiplied indefinitely, but I have already, I fear, entered too lengthily into this part of my subject I will therefore close the statistical data under Proposition 6 by quoting the following

1 Mortality from smallpox among the vaccinated doubtfully vaccinated and unvaccinated[36]

	Cases			Deaths			Mortality Per cent		
	Vaccinated	Doubtfully vaccinated	Unvaccinated	Vaccinated	Doubtfully vaccinated	Unvaccinated	Vaccinated	Doubtfully vaccinated	Unvaccinated
London Smallpox Hospital (1836-67)[37]	10 308	268	2 920	790	106	1 018	7 59	10 9	34 9
Metropolitan Asylum Board Hospital[38]	13,575	2,130	3,972	1 027	671	1 593	7 56	31 5	40 0

2 Mortality from smallpox among the vaccinated, doubtfully vaccinated and unvaccinated under 10

	Cases			Deaths			Mortality Per cent		
	Vaccinated	Doubtfully vaccinated	Unvaccinated	Vaccinated	Doubtfully vaccinated	Unvaccinated	Vaccinated	Doubtfully vaccinated	Unvaccinated
Metroplitan Asylum Hospitals[39]	1 291	359	1 812	[illegible]	102	745	1 83	28 4	40 2

Dr Lyon Playfair in a speech in the British House of Commons, June, 1883, said "On this point I would refer to the case of Leipsic, which for eighteen years prior to 1870, had zealously supported the anti vaccination movement, and during that period there had been but twenty nine deaths from smallpox, although vaccination had been greatly neglected in the town When the pandemic reached Leipsic in 1871 the town had a population of 107,000, and smallpox attacked 1,027 of this number, or 9,600 per millon of the population, and out of 3,892 children under 15 years of age, 715 died, being 30,000 per million"

"The statistics of the London epidemic were prepared with great care, and the mortality among the vaccinated was 90 per million inhabitants, while among the unvaccinated it was 3,350 per million In the hospitals 45 per cent of the unvaccinated and 15 per cent of the vaccinated died"

Comparative mortality of smallpox after smallpox, and of smallpox after vaccination

Authorities	Smallpox after smallpox			Smallpox after vaccination		
	No of cases	Deaths	Ratio of deaths to 100 cases	No of cases	Deaths	Ratio of deaths to 100 cases
Thompson Edinburgh	71	3	4 2	310	1	0 3
Chelsea Military Asylum	26	3	11 5	24	0	0 0
Heim Wurttemberg	39	14	35 8	147	42	28 5
Bosquet Marseilles	20	4	20 0	2 000	20	1 0
Gregory, London	9	2	22 2	789	46	5 8
Total	165	26	15 7	3 270	109	3 3

It thus appears that, while they who take smallpox a second time die in the proportion of 15 7 in the 100, they who take smallpox after vaccination die only in the proportion of 3 3 in the 100—a proportion absolutely lower than the mortality of the mildest disease

Borough of Sheffield, England In this Borough in an epidemic of smallpox during the years 1887 and 1888, Dr F W Barry, inspector of the Local Government Board, after having a house to house inspection made throughout these two years, gives the following report as the result of his investigation

VACCINATED	UNVACCINATED
In the borough of Sheffield there resided 268 397 persons who had been returned as vaccinated Of these 4,131, or 1 55 per cent, had been attacked by smallpox and 0 07 per cent died of the disease	There were 5,715 citizens of all ages returned as unvaccinated Of these 552, or 9 7 per cent, had been attacked by smallpox, and 4 8 per cent died
Of the 68,236 vaccinated children under 10 years of age 353 or 0 5 per cent contracted smallpox, and 6, or 0 009 per cent died	Of 2 259 unvaccinated children under 10 years of age 228 or 10 1 per cent, contracted smallpox and 100 or 4 4 cent, died
Of 196 905 vaccinated persons aged 10 years and upward 3 374, or 1 9, contracted smallpox and 194, or 0 10 per cent died	Of 3 429 unvaccinated persons aged 10 years and upward 322 or 9 4 per cent, contracted smallpox and 174 or 5 1 per cent, died

The proportions of unvaccinated and vaccinated who were attacked and who died of smallpox among the inmates of houses that were actually invaded by smallpox, that is where people were brought in actual contact with the disease, Borough of Sheffield, England, 1887-1888 Of course in the general population of the Borough a number of citizens were never brought into actual contact with infected persons or fomites

In the whole Borough of Sheffield 18,756 persons of all ages were enumerated as living in houses invaded by smallpox and of these 4,703 or 25 1 per cent contracted the disease, and 474 or 2 5 per cent died

The proportions of the population of the vaccinated and unvaccinated classes respectively, living in invaded houses in the entire Borough, who had been attacked by smallpox and who died of the disease were as follows

VACCINATED	*UNVACCINATED*
Of the 18,020 vaccinated persons of all ages enumerated as living in invaded houses 4 151 or 23 per cent, contracted smallpox and 200, or 1 1 per cent, died	Of the 736 unvaccinated persons of all ages enumerated as living in invaded houses 552 or 75 per cent contracted smallpox and 274, or 37 3 per cent, died

CHILDREN UNDER 10 YEARS OF AGE

VACCINATED	*UNVACCINATED*
Of 1,193 children under 10 years of age 953 or 7 8 per cent contracted smallpox and 6, or 0 1 per cent died	Of 263 unvaccinated children under 10 years of age 225 or 80 9 per cent had smallpox and 100 or 38 1 per cent died
Of 13 135 vaccinated persons aged 10 or upward 3,874, or 28 1 per cent, died	Of 169 unvaccinated persons 10 years old and upward 322, or 68 6 per cent contracted smallpox and 174 or 37 1 per cent died

On page 42 of Report of Royal Vaccination Commission the following facts are to be found giving the proportions of the population of the Borough of Sheffield of the vaccinated and unvaccinated classes respectively at these several age periods who at the end of the census had contracted smallpox, and who had died of the disease

IN THE TOTAL ENUMERATED POPULATION

VACCINATED	UNVACCINATED
Of 33 993 vaccinated children under 5 years of age 121 or 0 36 per cent, had been attacked by small pox and 1 or 0 003 per cent, had died	Of 1 981 unvaccinated children under 5 years of age 128 or 6 5 per cent had been attacked by small pox and 66 (exclusive of children under one month of age), or 3 3 per cent had died
Of 34 843 vaccinated children aged 5 but under 10 years 232 or 0 67 per cent *had been attacked* and 5 or 0 14 per cent had died	Of 278 unvaccinated children aged 5 but under 10 years 100, or 36 per cent had been attacked and 34, or 12 2 per cent had died
Of 32 965 vaccinated persons aged 10 but under 15 years 620 or 1 9 per cent, had been attacked and 11, or 0 03 per cent had died	Of 235 unvaccinated persons aged 10 but under 15 years 91 or 38 7 per cent, had been attacked and 32, or 13 6 per cent had died
Of 27,111 vaccinated persons aged 15 but under 20 years 979, or 3 6 per cent, had been attacked and 19 or 0 07 per cent had died	Of 282 unvaccinated persons aged 15 but under 20 years 84 or 29 8 per cent had been attacked and 53 or 18 8 per cent had died

The above facts are extracted from the testimony of F W Barry, M D, inspector of Local Government Board, Oct 8, 1889, pages 39 to 42 inclusive, Second Report of Royal Vaccination Commission of England, submitted to Parliament, May 29, 1890

---

[36] In the statistics of the metropolitan smallpox asylums the 'vaccinated are those who present marks however imperfect of a primary vaccination the unvaccinated" those who precent no marks, and in whose case it is admitted by the patients themselves or their guardians that they have never undergone the operation the doubtfully vaccinated those who present no evidence of vaccination but who profess to have undergone the operation or have no knowledge as to whether they have ever undergone the operation *It is evident that the* 'doubtfully vaccinated' are really unvaccinated'

[37] Marson Evidence *before the* Select Committee on Vaccination, 1871

[38] These include cases admitted into the following asylums Deptford 1875-81 Hampstead 1876-78 Homerton Smallpox Hospital 1871-82 Homerton Fever Hospital, 1876-77 and 1881-82 Stockwell 1882 *Vide* annual reports of the several hospitals For further figures consult report of board of health of the city of Philadelphia, 1872 papers on vaccination by Mr Simon etc

[39] Homerton Smallpox Hospital, 1871-80 Deptford Hospital, 1878, Stockwell Smallpox Hospital 1882

VACCINATED	UNVACCINATED
Of 44 788 vaccinated persons aged 20 but under 30 years 1 207 or 2 8 per cent, had been attacked and 69, or 0 15 per cent, had died	Of 884 unvaccinated persons aged 20 but under 30 years 98 or 10 6 per cent, had been attacked and 61, or 6 9 per cent had died
Of 92 011 vaccinated persons aged 30 and upward 899 or 0 97 per cent, had been attacked and 95, or 0 1 per cent had died	Of 2 028 unvaccinated persons aged 30 and upward 49 or 2 4 per cent had been attacked and 28 or 1 4 per cent, had died

On page 43 of the same report will be found the following tables as to the proportions of vaccinated and unvaccinated in the invaded houses by age periods

VACCINATED	UNVACCINATED
Of 2 151 vaccinated children under 5 years of age enumerated as living in invaded houses 121, or 5 6 per cent, had been attacked by smallpox and 1 or 0 05 per cent, had died	Of 154 unvaccinated children under 5 years of age enumerated as living in invaded houses 128 or 83 per cent had been attacked by smallpox and 66 (exclusive of children under one month old) or 42 9 per cent, had died
Of 2 339 vaccinated children aged 5 but under 10 years 232 or 9 9 per cent had been attacked and 5 or 0 21 per cent had died	Of 109 unvaccinated children aged 5 but under 10 years 100 or 91 8 per cent, had been attacked and 34 or 31 2 per cent had died
Of 2,196 vaccinated persons aged 10 but under 15 years 629 or 25 2 per cent had been attacked and 11 or 0 4 per cent, had died	Of 93 unvaccinated persons aged 10 but under 15 years 91, or 98 per cent, had been attacked and 32 or 34 4 per cent, had died
Of 2,370 vaccinated persons aged 15 but under 20 years 979, or 41 3 per cent, had been attacked and 19 or 0 8 per cent had died	Of 98 unvaccinated persons aged 15 but under 20 years 84, or 85 8 per cent had been attacked and 53 or 54 1 per cent had died
Of 3,274 vaccinated persons aged 20 but under 30 years 1,267 or 38 7 per cent had been attacked and 69 or 2 1 per cent, had died	Of 124 unvaccinated persons aged 20 but under 30 years 98 or 79 1 per cent, had been attacked and 61 or 49 2 per cent had died
Of 5 200 vaccinated persons aged 30 years and upward 890 or 17 4 per cent had been attacked and 95, or 1 8 per cent had died	Of 154 unvaccinated persons aged 30 years and upward 49 or 31 8 per cent, had been attacked and 28, or 18 2 per cent had died

NOTE — Those classified as vaccinated include all persons success fully at any period beyond thirteen days prior to the appearance on them of the eruption of smallpox As a matter of fact I do not think there is a recorded case in which smallpox quickly followed vaccination or re vaccination when the interval between the operation and the appearance of smallpox exceeded six or seven days Those classified as unvaccinated include all persons who have either never been success fully vaccinated or whose vaccination was performed for the first time within thirteen days of the appearance on them of the eruption of small pox In the vaccination census if a person stated that he was vaccinated that was accepted as correct if he stated that he was unvaccinated that again was accepted as correct A certain number were reported as vac cinated who really were unvaccinated " Barry, loc cit

Question 1988 Dr Barry continuing (see page 45) said I propose to read in very much the same manner as I have read with regard to the census data, the relations of vaccination and smallpox as indicated by the health office data I first of all take page 190 The total cases of smallpox reported to the health department to have occurred in the Borough of Sheffield during the period from the commencement of the epidemic to the 31st of March 1888, were 6 088 in number Of these it was stated that 5,035 were of the "vaccinated" as against 1,053 of the "unvaccinated" class In 589 cases, or 9 7 per cent, of the total of all classes attacked the disease proved fatal Of the 5,035 persons of the "vaccinated" class attacked, 246, or 4 9 per cent, died, whilst of the 1,053 persons of the 'unvaccinated" class attacked 343, or 32 6 per cent died In the "vaccinated" class smallpox is reported to have attacked 97 persons under 5 years of age, of whom 1, or 1 per cent, died, 243 between 5 and 10 years of age, of whom 6, or 2 5 per cent, died, 2 034 between 10 and 20 years of age, of whom 38, or 1 9 per cent, died 1,579 between 20 and 30 years of age, of whom 87, or 5 5 per cent, died, and 1,084 aged 30 years and upward, of whom 114, or 10 5 per cent, died In the "unvaccinated" class, smallpox is reported to have attacked 242 persons under 5 years of age, of whom 113 or 46 7 per cent, died, 184 between 5 and 10 years of age, of whom 39, or 21 2 per cent, died, 380 between 10 and 20 years of age, of whom 92 or 24 2 per cent, died, 169 between 20 and 30 years of age, of whom 65, or 38 5 per cent, died, and 78 aged 30 years and upward, of whom 34, or 43 6 per cent, died

Dr Barry, page 51, Second Report of Royal Vaccination Commission gives a tabular statement showing the fatality per cent of admissions in each hospital and all hospitals in Sheffield in 1887 and 1888, and says

From an examination of that table it will be seen that there is a general correspondence between the fatality rates which obtained in the several hospitals at the different age periods The figures with regard to the Lodge Moor and Ecclesall Bierlow Hospitals show the chief variations, but in the case of these hospitals the figures are very small From the summary of the figures with regard to all the hospitals, it appears that the total of 1 798 cases of smallpox, 256, or 14 2 per cent proved fatal Of the total number of cases, 1,351 were of the "vaccinated" as against 447 of the "unvaccinated' class Of the 1,351 persons of the "vaccinated" class admitted, 110, or 8 1 per cent, died, whilst of the 447 "unvaccinated ' persons admitted, 146, or 32 7 per cent, died Of the 1,351 persons of the "vaccinated" class admitted, 67 were under 10 years of age, and of these 1, or 1 5 per cent, died, 573 were aged 10 but under 20 years, and of these 13, or 2 3 per cent, died, 426 were aged 20 but under 30 years, and of these 42, or 9 9 per cent, died, and 285 were aged 30 years and upward, and of these 54, or 19 per cent, died The whole of the persons of the "vaccinated" class who died had been vaccinated in infancy only, with one exception, and the figures show a greater liability to fatal termination with increasing years Of 447 persons of the "unvaccinated" class admitted, 101 were under 10 years of age, and of these 34, or 33 7 per cent, died, 205 were aged 10 but under 20 years, and of these 56, or 27 3 per cent, died, 100 were aged 20 but under 30 years, and of these 41, or 41 per cent, died, and 41 were aged 30 years and upward and of these 15, or 36 6 per cent, died In the hospitals of course all the patients were under the same conditions, they were not being treated in different class houses, some in good ones and some in bad ones, but they were all being treated under the same nursing and with the same general surroundings, and, as I here note in the report, "except during the first few months of the epidemic, very few of the milder cases found their way to the hospitals, and consequently the proportions of severe and fatal cases were larger there than amongst the population as a whole " Then dealing in the same way with the fatality of the cases in hospital taking all ages Taking children aged 0 10 "For each individual vaccinated child 0 10 years of age suffering from a fatal attack of smallpox, 22 4 unvaccinated children died of that disease " Taking persons from 10 to 20 years of age "For each individual vaccinated person 10 to 20 years of age suffering from a fatal attack of smallpox, 12 unvaccinated persons of similar age died of that disease " Then as to persons from 20 to 30 years "For each individual vaccinated person aged from 20 to 30 years of age suffering from a fatal attack of smallpox, 4 1 unvaccinated persons of similar age died of that disease "

(*To be continued*)

SOCIETY PROCEEDINGS

American Association of Obstetricians and Gynecologists

Ninth Annual Meeting held in Richmond, Va , Sept 22-24, 1896

FIRST DAY—MORNING SESSION

The Association was called to order at 10 A M by the President, Dr JOSEPH PRICE of Philadelphia

After the usual preliminary exercises, the reading of papers was proceeded with

Dr JOHN M DUFF of Pittsburg, read a paper entitled

PELVIC DISEASES AND THEIR PRINCIPAL CAUSES, WHAT SHOULD THE LAITY BE TAUGHT CONCERNING THEM?

He said that notwithstanding the fact that some of the prominent members of the medical profession had, in talks to the galleries, held the gynecologists up for ridicule and criticised them severely, he did not think any apology was due either the profession or the public for the character, or results of pelvic surgeons Those members of the profession who had been devoting themselves to the care of diseases peculiar to women had in the face of revilings and professional and public prejudice worked patiently and persistently until they were now obtaining results of which they may well feel proud, results far beyond what the most sanguine expectations of the hardy pioneers of a quarter of a century ago led them to hope for They were to day charged with irrational radicalism, with an operative mania, which was gratified without a proper consideration of the ultimate benefit to the patient Entreatingly they were urged to adopt more conservative measures and thus stop the wholesale mutilation which was going on at present, which it is claimed is neither scientific nor humane Sentiments such as these, endorsed by men of reputation were eagerly taken up by the lay press as sensational news and advertised by pretenders as an endorsement of their methods of practice, and thus the laity, in the opinion of Dr Duff are taught false notions regarding the nature of pelvic diseases and their treatment That there is a great amount of mutilation connected with pelvic surgery, he would not deny but that regular pelvic surgeons were guilty of reckless despoliation was not, he thought, susceptible of cons could scarcely be held accountable for eral practitioners, and for the work of ignorant egotists and pretenders, who with brazen effrontery undertake operations of which they are not qualified by character or education, the pelvic surgeons disclaim all responsibility

During the period of the evolution and upbuilding of pelvic surgery no doubt much of the work was crude, and perhaps too much was done by over zealous operators That at this day, through mistaken diagnosis operations are sometimes needlessly performed, no one would have the hardihood to deny, but that such cases are as frequent as some critics say they are, Dr Duff could not believe He said the true pelvic surgeon was governed by nobler purposes, by more elevated aims Conservatism in its true sense, the saving of life, relief from pain and the curing of the patient, was his watchword Dr Duff then dwelt at length upon various pathologic conditions which demand the attention of the pelvic surgeon

Dr **Walter B Dorsett** of St Louis, followed with a paper on

DECEPTIVE SIMILARITY OF SIGNS AND SYMPTOMS OF INTRA-ABDOMINAL DISEASE, WITH CASES

In order to arrive at a conclusion and to formulate a diagnosis in a given case, be it medical or surgical, the practitioner must exercise care and judgment in the consideration of such signs and symptoms as are presented Each should be weighed, and mental annotations taken as to their value individually and collectively

Dr Dorsett directed attention to the importance of the family and personal history of patients, to the pulse and temperature, the knoweldge to be gained by manual examination the use of analgesics, etc

Regarding the exploratory incision, it should not be regarded as an evidence of ignorance, but as a legitimate means of diagnosis, and the off hand diagnostician, or the surgeon who never makes mistakes, should be looked upon with, at least, a grain of suspicion To illustrate his statements, three interesting cases were reported, one of which we give in full

Mrs M, aged 28, married eight years, no pregnancies, was seen by Dr Dorsett about a week after having recovered from an attack of malarial fever Temperature 99, pulse 90, tongue slightly coated and a tendency toward diarrhea Complained of general abdominal tenderness, palpation of abdomen revealed a slightly more tender spot at McBurney's point, no swelling or tumefaction could be felt A vaginal examination revealed a retroversion with fixation, no tubal enlargement nor tenderness could be made out No vaginal discharge Diagnosis Gastro intestinal irritation with chronic inflammation of pelvic contents, diarrheal mixture was prescribed and patient was told that further attendance would probably not be necessary Four days subsequently the temperature was 99 8 F, pulse 100, abdominal palpation revealed a distinctly tender spot with some swelling at McBurney's point Patient stated that she had eaten heartily of Wienerwurst the day before, and had been awakened during the night by cramps at the navel Bimanual examination was again resorted to with negative result Appendicitis was diagnosticated at this visit, first stage Dram doses of salts were prescribed, and the patient was urged to go to the hospital, but refused The next day she was seen and found sitting in a rocking chair, and aside from slight tenderness over abdomen, was feeling quite comfortable Salts acted freely Bimanual examination again gave negative results, temperature 99, pulse 100 Patient was ordered to bed and advised to keep quiet The case was regarded as better and thought to be out of danger The following day the pain became more severe and the patient came to the hospital of her own accord Upon examination the right iliac fossa was found to be exceedingly tender and fluctuating Vaginal examination revealed nothing aside from what was found at the previous examination Temperature 103, pulse 130 Diagnosis Ruptured appendiceal abscess She was anesthetized and placed upon the table and a section made in the median line The large sac was found on the right side filled with blood and clots, and when washed out a rent of the posterior layer of the broad ligament was found which communicated with another rent in the Fallopian tube Appendix perfectly healthy, and was not disturbed A thorough washing out of the sac was done and ligation of the tube with a portion of the broad ligament, a glass drainage tube was introduced Notwithstanding the utmost care, the temperature remained high, pulse became worse, the abdomen became distended, and the patient died on the third day

Postoperative diagnosis Ruptured tubal pregnancy without the usual symptoms There was no history of shock, no cessation of menstruation, or nervous symptoms of pregnancy No passage of decidua, no vaginal discharge of any kind, but in its stead a good history and train of signs and symptoms of inflammatory disease of the appendix

Dr **Rufus B Hall** of Cincinnati read a paper entitled,

THE MOST POTENT CAUSES OF PELVIC INFLAMMATION

He claimed that septic infection following labor or abortion or gonorrheal infection, was the cause in almost every instance He says there will always be some cases of septic infection following labor, which are in nowise due to infection from the attendant, injury to small pelvic tumors, etc The retention of the products of conception in abortion is a very frequent cause He advises completely emptying the uterus at once after abortion The Doctor believes the most frequent cause to be gonorrheal infection conveyed to the woman from a latent gonorrhea of her husband The more he sees of the ravages of gonorrhea, the more he is convinced of the fact that the profession is derelict in its duty to its patients in the dissemination of knowledge upon this subject The teaching of a few years ago that gonorrhea in the male could be easily and speedily cured by a little balsam of copaiba, or oil of sandal wood, with mild astringent injections, and that the patient was well as soon as the purulent discharge ceased, is false doctrine and must be corrected This must be done by the family physician Dr Hall does not stand alone when he says that he has on many occasions been compelled to remove suppurating tubes and ovaries from women who had contracted the disease from their husbands, who believed themselves well when married He has no hesitation in saying that gonorrhea is more destructive to women than syphilis, and believes it is the duty of every physician to impress upon his male patient the fact that he is not well as soon as the urethral discharge disappears He is a firm advocate of legislation upon this, believing that every man should have a certificate from the health officer of freedom from syphilis and gonorrhea before he is granted a marriage license

Dr **Henry Carstens** of Detroit in discussing the three preceding papers, said that when prominent ministers of churches consulted physicians and asked them to produce abortion on their wives he became discouraged, and thought it was love's labor lost Still the gynecologist should keep on preaching against the evils attending the production of abortion Regarding Dr Dorsett's paper, the difficulty attending diagnosis in some cases was exceedingly great The gynecologist should exhaust his diagnostic resources before resorting to abdominal section The too frequent opening of the abdomen stimulated incompetents to do likewise, and as a consequence results were disastrous, eventually reacting on gynecologists

Dr **W E B Davis** of Birmingham, Ala, does not believe that gonorrhea plays so important a part in the production of pelvic inflammation as was heretofore taught One's conception of cases of pelvic trouble depends largely upon the class of practice he has The cases met with in dispensary practice are different from those encountered in private work He believes that fully 50 per cent of the cases of pelvic inflammation are due to puerperal infection, either at the time of delivery at full term or premature delivery As to tubercular trouble, more importance is being attached to it as a cause of pelvic inflammation than it deserves Those who did considerable operative work knew that only a small per cent of cases have their origin in tuberculosis

Dr **James McFadden Gaston** of Atlanta (by invitation) called attention to the prophylactic management of cases of pregnancy prior to the period of confinement Extreme hygienic precautions might warrant in some instances the use of antiseptic washes prior to labor, but as there was a great tendency on the part of some members of the profession to resort to measures which are regarded as precautionary in the way of preparing a woman for labor and using washes in advance of confinement, it struck him this was altogether out of place, inasmuch as there was a normal condition of things, and nature should be allowed to take its course unless there were ample reasons for interference

Dr **Ernest S Lewis** of New Orleans cited a case in connection with errors that sometimes arise in the diagnosis of abdominal tumors He operated on a patient last winter for what he supposed at the time was a small ovarian tumor, but after the abdomen was opened it turned out to be a retroverted gravid uterus

Dr **F D Thompson** of Fort Worth, Texas, would like the essayists to have gone more fully into the point as to when it was safe for men to marry and have intercourse with their wives, who had been the subjects of gonorrhea Many cases of gonorrhea occurred in married men, and the gynecologist had before him all the ills and consequences incident to this disease How long shall such men abstain from sexual intercourse? These points should be dealt with more fully and explicitly

Dr **Lewis S McMurtry** of Louisville considered the view enunciated by Dr Hall as to gonorrhea and its relations to marriage impracticable Regarding the exploratory incision for diagnostic purposes, a small opening was not always sufficient The incision should be sufficiently large to allow the surgeon to thoroughly explore the abdominal cavity to detect such pathologic conditions as might be present

Dr L H **Dunning** of Indianapolis cited cases of the impracticability of making a small incision for the detection of intra abdominal pathologic conditions He favors an exploratory opening sufficiently large to make a thorough search

Dr A H **Cordier** of Kansas City, Mo , said, regarding the possibility of making diagnoses in intra abdominal pathologic conditions, that in 80 per cent of the cases this could be done by painstaking efforts

Dr **Edwin Ricketts** of Cincinnati agreed with the previous speakers that it was exceedingly difficult to diagnosticate intra abdominal lesions previous to opening the abdomen, and sometimes the surgeon did not know the nature of the growth even after the abdomen was opened Cases illustrating the great difficulty attending diagnosis of intra abdominal growths were cited

Dr E F **Fish** of Milwaukee said that while he did not believe in promiscuous exploratory laparotomy, he could recall one case in particular in which the operation saved the patient's life

Dr **Richard** H **Gibbons** of New York City thought many of the cases dealt with in the papers were due to puerperal contamination, or in some instances to laceration of the cervix, as had been pointed out by Emmet He believes that Noeggerath gave us the keynote to the class of infection produced by gonorrhea Relative to diagnosticating intra abdominal diseases, there was no particular symptom that was pathognomonic Dr Gibbons pointed out the unreliability of McBurney's point, of which so much had been said and written, and called attention to an article written by him and published in the *New York Medical Journal*

Dr **Howard** W **Longyear** of Detroit emphasized the importance of educating the laity in regard to gonorrhea He believes the teachers of our public schools should be empowered to impart the necessary knowledge regarding the dangers of this disease and its consequences

Dr **George Ben Johnston** of Richmond presented the specimen of an ovarian tumor, the first removed under Listerism in the State of Virginia so far as he had been able to ascertain The patient was an unmarried woman, 26 years of age The tumor was removed March 19, 1879 The tumor with the sac and fluid contents weighed thirty four pounds The operation was performed under the spray and with the elaborate dressings recommended by Lister, etc The patient died, however, from sepsis In November of the same year he was consulted by Mrs M , whom he presented to the Association for what turned out to be an enormous unilocular ovarian tumor Her measurements were 6 feet, 4 inches around the abdomen at the umbilicus, and 3 feet, 2 inches from the ensiform cartilage to the pubes The contents of the tumor and sac weighed ninety six pounds This operation was performed at the patient's house with the same care as that of the previous one

TUBO OVARIAN CYSTS WITH INTERESTING CASES

Dr **Albert Goldspohn** of Chicago read a paper on this subject By tubo ovarian cyst is meant a non purulent sac whose walls are composed, in variable *proportion, of* the walls of the Fallopian tubes and those of some cystic ovarian or parovarian formation with the coalescence of two or more cavities, at least one from each, into one, by a free communication The fluid contents of such a sac may be serous or hemorrhagic, or may partake in variable degree of the qualities and characteristics of the fluid contained in glandular ovarian cystomas The fimbriæ of the abdominal *ostium* of the tube may be distinguished or not upon the inner or on the outer side of the ovarian portion of the sac, or they may have coalesced with other structures to form some portion of the walls of the united sac The ovarian element in this formation can have originated from a hydropic Graafian follicle, a cystic corpus luteum, from the primordial glandular ducts of Pflueger in the ovary, or from the parovarium. In order to exclude a large number of ordinary tubo ovarian conglomerates we need to recognize the following minimum requirements in distinguishing a tubo ovarian cyst 1, the participation of the tube, which is easy enough from its position and connections, 2 to prove the participation of the ovary by demonstrating some ovarian tissues in the wall of the sac, 3, that their cavities are united by some opening through which the mucous membrane of the tube is continuous with the lining of the ovarian cyst or follicle Applying this standard the author has been compelled to exclude a number of cases that have been mentioned as such cysts, because the three points were not proven in each of the cases

The first description of a tubo ovarian cyst was given by Blasius in 1834, but the correct name was proposed by Richard in 1853, who spoke of 'kysts tubo ovariens" in demonstrating a number of postmortem specimens The total number of authenticated cases that the author has been able to find in literature is thirty eight by twenty five different authors Dr Goldspohn reported three interesting cases, and called attention to some interesting features in connection with the anatomy as influencing intermittent profluent discharges and showing the inflammatory element in their causation From a study of specimens, from the results of experience, and from the arguments of the best authors, the author deduces the following conclusions

1 Tubo ovarian cysts come to pass in consequence of a plastic inflammatory union between a Fallopian tube and the adjacent ovary, after either or both of these organs and the intervening peritoneum have experienced a non purulent pathologic change of a cystic character The septum intervening between the two lumina disappearing in consequence of pressure *atrophy from the tension of liquid confined* to one or both sides of it

2 This union of a distended tube cavity may occur also with that of a parovarian cyst (v Ott), or with that of a peritoneal pseudo cyst (Zedel)

3 In those rarer cases in which the fimbriæ are really found floating in the interior of the main cyst cavity, we must assume either the congenital anomaly of an "ovarian tube," as was seen by Schneidemahl in a mare, as a vitium primæ formationis, or that an ovarian cyst or follicle cyst ruptured, and the abdominal end of the tube dropped into the rent and was united to its edges by inflammatory action, thus making a joint cyst and tubal cavity

Dr **Walter** B **Chase**, of Brooklyn, followed with a paper entitled

MIXED TUMORS OF THE OVARY

Mixed tumors of the ovary have a peculiar interest, *for* the reason that if small, they are often difficult of diagnosis These tumors of the ovary may be made up of a variety of cysts, or may be a combination of cysts and solid growths The etiology of tumors as a whole is a matter of great importance, both in the relation to diagnosis and treatment

The question of what constitutes a tumor might be considered *with profit* Senn, *in* his *recent classical work* on the "Pathology and Surgical Treatment of Tumors,' defines a tumor as "a localized increase of tissue proliferation of embryonic cells of congenital or post natal origin " An important fact concerning true tumors is that they never disappear except by removal or destruction Benign tumors always remain local, while malignant ones are disseminated by migration or transportation of their peculiar cells, and they always originate as benign or malignant growths If the tumor matrix is made up of embryonic cells of the lowest development, there is greater liability to malignant growth, than if from tissues susceptible to the highest physiologic type of development

Retention cysts of the ovary are not tumors in a technical sense, and they never attain large size Large ovarian cysts are most often cyst adenomas and are not developed from Graafian follicles but arise from the embryonic structure

It would seem from what has been said that the genesis of simple and mixed tumors is divested of much that was misleading and contradictory and reduced to a rational basis It also demonstrates with great clearness that tumors are not only of local origin, but at their inception are congenital

The case reported, which was operated upon by the author at St John's Hospital, Aug 4, 1894, is reported by Dr H P De Forest, pathologist to the Methodist Episcopal Hospital, was a mixed tumor of the left ovary, consisting of a large cyst adenoma, containing about two gallons of clear straw colored fluid, a *dermoid intimately* united with *the* cyst-adenoma containing less than a quart of fluid, leaving true bony plates in its wall, and numerous encysted papillomas encrusted within the walls of both cysts

AFTERNOON SESSION

Dr A H **Cordier** of Kansas City, Mo , read a paper on

MOVABLE KIDNEY LOCAL AND REMOTE RESULTS

in which he drew the following deductions 1 A movable kidney often produces a dilatation of the stomach with all the accompanying symptoms of a disease of that organ 2 It is a *fruitful source of* gallstones, because of the pedicle producing a partial obstruction of the common duct. 3 The bending of the ureter often gives rise to a hydronephrosis This, in turn, is sometimes converted *into* a pyonephrosis 4 It may produce death by a complete strangulation by a torsion of the vessels and ureter 5 By dragging on the abdominal aorta and kinking the vena cava, a condition simulating an aneurysm of these vessels may be produced 6 Pain of a referred character to the region of distribution of the spinal nerves is often induced by a movable kidney's disturbance of the abdominal plexus 7 A general nerve exhaustion (neurasthenia) is often induced by the interference of this condition with digestion, assimilation and elimination 8 Nephrorrhaphy is a safe and effective surgical procedure 9 All cases of movable kidney, if accompanied by symptoms pointing to the kidney as their source should be operated on 10 In summing up the local and remote results of this now often recognized condition, the author thinks the correctness of the deductions has been frequently demonstrated by the disappearance of each and every symptom after a restoration and retention of the kidney in its normal position 11 Symptoms are not to be relied upon in making a diagnosis of movable kidney The physical examination is the only trustworthy guide

THE LIMITS OF NEPHRORRHAPHY

was the subject of a paper by Dr Hugh M Taylor of Richmond, Va He conceded the frequency of nephroptosis Since he had been systematically looking for movable kidney, he has found it so frequent in its occurrence that he no longer regards the experience of Glenard, Linduer, Edobohl and Noble as unique His opinion is equally fixed that only a small proportion of the cases met with give rise to symptoms or suffering, ill health or death, and consequently a majority of cases do not call for nephrorrhaphy He favors the classification of nephroptosis under three clinic heads

1 Patients who have displaced kidney do not know it and suffer no inconvenience whatever from it This type he thinks represents by far the largest class

2 Patients with displaced kidney, who may or may not know it, who suffer from gastro enteric discomfort and perhaps a long train of vague neurotic disturbances In this type he thinks we find the largest class calling for operative interference

3 Patients with movable kidney, who are subjects of occasional or frequent mild or severe attacks of renal crises This last mentioned is he thinks the least frequent type met with, but the urgency of the symptoms more frequently demands operative interference

Nephrorrhaphy for the relief of gastro enteric disorder is limited by our ability to tell to what extent the disorder is due to renal ptosis per se or to enteroptosis, or to some one of the many well known etiologic factors of gastro enteric disorder Nephrorrhaphy for the relief of the condition of Deitl's or renal crises must be limited by one's success in differentiating between this condition and that of gall tract, appendicular and kidney colic due to nephrolithiasis He accepted as logically sustained the conclusion that the Deitl s or renal crises is due to a kink or twist of the ureter with retained urine in the ureter and pelvis of the kidney Apart from the violent paroxysms of pain (the renal crises) the tendency of ureteral twist and urinary obstruction to induce hydronephrosis and in exceptional instances pyonephrosis, rendered operative interference more imperative in this class of cases His protest was not against nephrorrhaphy, but only its abuse He conceded the value of operative interference in many selected cases but deprecated the tendency toward operative interference merely because the kidney is movable

Dr George Ben Johnston of Richmond, Va, said that some years ago his attention was called to the subject by encountering several cases of movable kidney that had been unobserved either by him or the physician who preceded him in the treatment of these cases for obscure nervous and gastro intestinal disturbances, and when he observed the similarity of symptoms in the first three cases which he saw, he was obliged to associate those symptoms with the presence of movable kidney He prevailed on these women to be operated upon for movable kidney and in all three cases the results were most gratifying

Dr L H Dunning of Indianapolis, was greatly interested in the subject, for the reason that in 1880 he resorted to operative procedures for the cure of floating kidney, and in connection with this work he sought to determine if possible some of the causes which led to movable kidney He emphasized the importance of differentiating between floating and movable kidney, the former being always congenital, the latter acquired to a greater or less extent He found by his investigations that the partially fixed condition of the kidney depends upon three or four causes, the two principal ones of which were its position behind the peritoneum, and second the fact that it had an envelope of cellulo adipose tissue A little further investigation showed that the perinephritic cellulo adipose tissue was composed of two parts, one fixed, the other movable The normal kidney had a range of motion of from one half to three quarters of an inch in its fatty envelope

Dr Thos B Eastman of Indianapolis, reported the case of a woman, 25 years of age, who came to him with the symptoms of appendicitis She also had considerable albumin in the urine Operation showed that the appendix was firmly adherent to the kidney It required considerable force to liberate it As soon as liberated the kidney bounded back into place as though it were rubber The appendix was removed, the albumin in the urine ceased, and the woman made an uneventful recovery

Dr James McFadden Gaston of Atlanta, directed attention to the possibility of movable kidney being mistaken for enlarged gall bladder The gall bladder is capable of being pushed back into the lumbar region and carried around in front in just the same manner as a floating kidney It behooved gynecologists to look into this phase of the matter

Dr W E B Davis of Birmingham, had seen a number of cases of movable kidney, and said that at the Charleston meeting of the Southern Surgical and Gynecologic Association there was quite a difference of opinion as to the frequency of the condition He believes that movable kidney is a condition which does not require in all cases operative interference Of the number of cases he had seen he had only operated on a few

Dr I S Stone of Washington, D C, related the case of a woman who, after the operation of nephrorrhaphy had been performed, gained twenty five pounds in flesh In many instances this procedure brought color back to the cheeks of patients and made them feel well He had never seen such gratifying results from any other operation in surgery except perhaps from the removal of an ovarian tumor The patients made rapid improvement after the operation

Dr Joseph Price of Philadelphia, said his experience was somewhat limited in operating for movable kidney The improvement in the condition of patients so operated upon was rapid, but there was such a thing as operating too much upon cases of movable kidney

Dr J Henry Carstens of Detroit, said the line should be drawn between movable and floating kidney The trouble which arose from floating kidney consisted of a twisting of the ureter and consequent obstruction

Dr Richard H Gibbons of New York, detailed an operation which had been devised and recommended by a foreigner for holding the kidney in place in its newly made position

TREATMENT OF PERIUTERINE SEPTIC DISEASES

Dr W E B Davis of Birmingham, Ala, read a paper on this subject Only recently has the extremely radical procedure of hysterectomy been practiced in this country for septic diseases of the internal genitals A wave which had its origin in Paris at the hands of Péan, aided by Richelot, Segond, Jacobs and others, reached our shores three years ago and has found a considerable following among our leading operators The claim is made that there is no use in leaving the uterus behind after the removal of the appendages, in every operation for septic diseases of the female generative organs which demands the removal of the tubes and ovaries, hysterectomy should also be performed, unless there are plain contraindications forbidding it

It should be the aim of the surgeon to preserve everything consistent with thorough surgical work, and not to sacrifice important organs because it can be done with only small mortality We are told that the uterus has no function after the removal of the appendages, but this has not been demonstrated, and on the contrary we know that the sexual life of the woman is very much better preserved by leaving the uterus, and that the mental effect is also much better A slow convalescence, or even a second operation is preferable to its removal unless very much diseased It is a reflection on the correctness of the reports of complete recoveries of such a large per cent of the cases by most excellent surgeons, when the uterus was not removed, to accept the argument now being made in favor of hysterectomy in all these cases As stated by Dr Davis at the last meeting of the American Medical Association, he could not agree with Dr Sutton and others that pus in the tubes was due to gonorrhea in 75 per cent of cases He thought that puerperal infection was rarely the cause of more than 50 per cent Tubercular infection was rarely the cause and was not so important as he claimed However, the importance attached to gonorrhea was against the argument for the removal of the uterus, as the infection from this source was not deep and could be removed with the curette Because some patients were not completely cured by the removal of the appendages was no argument for hysterectomy in every case where the bilateral operation was required, for nearly all these could be relieved by a thorough curettage Some large uteri would require in addition to this a high amputation of the cervix, and only a small number would need a hysterectomy

Vaginal incision for the drainage of pus in the pelvis, not confined to the tubes, was a most valuable method of treatment in a well recognized class of cases, and had been practiced for a long time with gratifying results A large number of these cases require no further surgery More recently large pus tubes and ovarian abscesses had been incised and drained through the vagina with permanent recoveries in a good proportion of cases The uterus should always be curreted at the same time These were the very cases where the vaginal operation and hysterectomy had been recommended so highly by the French surgeons Yet a considerable per cent of these cases could be relieved by vaginal incision and drainage The object of the surgeon should be, not so much toward still further reducing the death rate from the operation, but to relieve the cases and preserve as far as possible organs which had so much to do with the woman's health and happiness

Dr L H **Dunning** of Indianapolis followed with a paper entitled

SHALL HYSTERECTOMY BE PERFORMED IN INFLAMMATORY DISEASES OF THE PELVIC ORGANS

The author discussed only that form of inflammation of the pelvic organs and tissues denominated diffuse pelvic inflammation, and drew the following conclusions

1 We recognize the utility of hysterectomy in a small percentage of bilateral suppuration of the tubes and ovaries in which the uterus is distinctly septic, and in cases of septic uteri which can not be cured by other means after bilateral salpingo oophorectomy

2 We oppose hysterectomy as a rule in inflammatory diseases of the pelvic tissues upon the following grounds, viz (*a*) The uterus is the central organ of the reproductive system and should not, except upon palpable and urgent cause be extirpated (*b*) It is only in rare cases that the uterus is so far diseased as to resist the curative effects of appropriate treatment (*c*) The removal of the uterus profoundly affects the nervous system and emotional nature of young women deprived of this organ (*d*) We oppose the removal of the uterus from anatomic reasons, to wit As a result the vagina is shortened, the anatomic relations of the bladder, sigmoid and rectum are changed, the elasticity of the pelvic diaphragm is greatly diminished or entirely removed, the elastic tissue being largely replaced by sensitive scar tissue (*e*) In married women it often disturbs the sexual relations of husband and wife and is apt to induce mental depression (*f*) Vaginal hysterectomy compels the use of drainage because of the necrosis of tissue and suppuration induced

SHALL THE UTERUS BE LEFT IN SITU IN EXCISION OF THE ADNEXA?

This paper was read by Dr E F **Fish** of Milwaukee, Wis The paper was a general defense of the uterus and an argument in favor of leaving it in situ, if sound, after excision of the appendages It takes up and considers the pathologic conditions requiring hysterectomy after salpingo oophorectomy, as well as the conditions which do not require it The author argues against all operations which leave a degenerate uterus, such as Hegar's, Tait's, Martin's and Robinson's, except under extreme conditions, and concludes thus 1 That whenever it becomes necessary to excise the uterine adnexa, if the uterus is sound, leave it 2 Whenever we excise the tubes and ovaries, and the uterus, though in a pathologic condition, in our judgment will yield to treatment, leave it 3 Whenever it is necessary to do an abdominal hystero salpingo oophorectomy and the cervix is healthy, do a supravaginal amputation, as this leaves the vaginal vault intact 4 Whenever it is necessary to do a supravaginal amputation, suspend the cervix to the stumps of the broad ligaments, or anchor it to the abdominal wall to prevent prolapsus vaginæ (Baldy) 5 Whenever it is necessary to do a general ablation, and the cervix uteri is unsound take the entire organ because of the danger of carcinoma 6 Whenever a subserous or interstitial myoma can be removed without too great damage to the uterus, do a myomectomy and leave the organ 7 Whenever we excise the appendages and leave the uterus, ventral fixation is not an unsurgical operative conclusion

The author's reasons for leaving the uterus were 1 That it helps to maintain the woman's sexual integrity 2 It relieves the patient of much mental strain and is a prophylactic measure to neurasthenia, melancholia and insanity 3 It tends to maintain the family ties unstrained 4. It obviates the possibility of vaginal hernia, cystocele and proctocele and delays vaginal atrophy, and last of all, it holds up and prevents shortening of the vagina

A spirited discussion followed the reading of the above there papers, and was participated in by Drs L S McMurtry John M Duff, Joseph Price, J Henry Carstens, Albert Goldspohn, George H Rohé, James F Baldwin, A B Miller, Walter P Manton, J W Bovee, Rufus B Hall, W E B Davis, E F Fish , some favored the abdominal and some the vaginal route

Second Day—Morning Session

Dr J W **Long**, of Richmond, Va , contributed a paper entitled

DYNAMIC ILEUS

Intestinal obstruction had been variously classified, but Dr Long regarded the classification adopted by Murphy as the simplest and the most rational 1 Adynamic ileus, always the result of intestinal paralysis, due to varying causes, may be clearly illustrated by such cases as those following injury to the spinal cord and paralysis due to peritonitis 2 Dynamic ileus This variety formed the subject of the paper and was discussed in detail 3 Mechanical ileus embraced such common lesions as strangulated hernia, intussusception, fecal impaction etc

We report one of Dr Long's cases herewith Mrs C , was brought to him on Mav 27, 1896 She is 21 years old, married three years, but never pregnant She is rather below the medium size and height In temperament she is of the spoiled child type not hysterical but rebellious It was with great difficulty that she could be induced to have any local treatment or even take her medicines After admission to hospital her obstreperous disposition required all the tact and firmness of a sagacious nurse Early in April of this year the patient had malaria followed by delayed menstruation, pelveo abdominal pain and obstinate constipation The malaria and menstrual disturbance yielded promptly to treatment, but the abdominal pain continued and gradually the ileus symptoms became more and more pronounced After exhausting every other measure to move the bowels the patient was given chloroform and by means of a Rickett's tube he succeeded in washing away a quantity of fecal matter Notwithstanding there was no improvement, the nausea and vomiting recurred oftener and were more distressing, the pain and tenderness became worse and a marked degree of tympany supervened When she was brought to the hospital there had been no movement of the bowels for four weeks excepting what was washed away with the colon tube while the patient was anesthetized The history justified the diagnosis of intestinal obstruction, while the urgent symptoms demanded an immediate operation The abdomen was opened by a median incision No mechanical obstruction could be found, although a careful search was made along the whole length of the intestine The bowel was moderately distended with gas and congested A singular feature, however, was that at three points, two in the ileum and one in the sigmoid flexure, the canal was constricted sufficient to constitute obstruction In the ileum one of the constrictions was about 15 inches from its lower end and 6 inches long, the other was nearer the jejunum and about 4 inches long The lumen was not entirely closed at either point, but was greatly reduced, being less than half the normal size, while the diameter of the remaining portions of the bowel was increased on account of the distention with gas No peristalsis was observed, but the contracted portions could be dilated by "milking," the intestinal contents along In the sigmoid the limitations of the contracted portion were not so sharply defined, but the lesion was just as evident The walls were thickened and the caliber much diminished Incidentally a small ovarian cyst on the right side was discovered and removed As the intestine had been handled a good deal the abdomen was flushed with normal salt solution The incision was closed with two tiers of sutures, silk for the peritoneum, and interrupted silver wire for the remaining layers The recovery was most satisfactory in every way The bowels responded to the usual laxatives and enemas on the second day, and from the first to last there was not a hitch in her convalescence The patient left the hospital in four weeks and three weeks thereafter took a trip to Alabama There could be discovered no evidence of lead or ptomain poisoning

SPONTANEOUS RUPTURE OF UTERUS DURING LABOR AT TERM, WITH SPECIMEN

A paper on this subject was read by Dr B M **Hypes**, of St Louis

Mrs O aged 31, of German parentage, general health good previous to birth of first child No history of any constitutional disease About one year after marriage aged 26 years was delivered of a seven and one half months child which lived but a few minutes This labor was easy, lasting about six hours The midwife in attendance failed to get the after birth which was removed by the family physician twenty hours after the birth of the child by means of his hand and the curette The woman then suffered for six weeks with a severe case of metro peritonitis From this time her health remained impaired, and for the next few years she was a sufferer from general debility, impaired digestion, and a "sore spot" in the hypogastrium Four years from the birth of her first child she again became pregnant During gestation, her general health was much improved She exhibited no functional disturbances, her only complaint was the sore spot over the fundus of the uterus and to the right of the median line Labor pains began Sept 16, 1895, at 10 P M, at full term The family physician was called, found labor in progress, vertex presentation, with normal condition of mother and child The pains were slight and progress slow At 2 A M, September 17, he gave a dose of morphin and went home At 9 A M, upon his return he found the patient comfortable, with occasional slight labor pains He left the house with injunction to call him when signs of labor became pronounced Patient remained quiet during the day Suddenly at 3 P M, she was seized with violent vomiting, followed by the most excruciating pains in her abdomen associated with rolling and tossing in bed, gasping for breath, faint feelings, pallid face and rapid exhaustion, in short, the usual symptoms of abdominal shock The family physician was at once sent for and upon his arrival, at 4 P M found her in complete collapse with convulsive seizures The symptoms, with vaginal and abdominal examination, revealed to him this dreadful condition The presenting part receded, the womb empty, and the child plainly felt in abdominal cavity The patient had suffered spontaneous rupture of the uterus He at once dispatched for surgical aid, but by the time the surgeon, Dr Meisenbach, arrived, the patient was moribund Still with the hope of saving the child, laparotomy was hastily performed, and the child, which had escaped entirely into the abdominal cavity, was extracted from a mass of blood and amniotic fluid It had ceased to live, and continued efforts at resuscitation failed to cause it to breathe The child was fully developed, male, weighed six pounds, and was 18 inches long The uterus, when removed from body, presented the following condition A rupture through fundus superiorly, extending from half an inch from the entrance of one tube to an equal distance from the entrance of the other, the walls, at place of rupture, were comparatively thin Placenta located at middle third of uterus, anteriorly and to the right, where the walls were much thickened Vaginal portion of the cervix almost obliterated as at term, and dilated for the ready admission of two fingers The lower zone of the uterus exhibited no thinning or formation of Bandl's contraction ring, no disease of tubes, ovaries, or placenta A microscopic examination was made soon after rupture and revealed fatty degeneration of tissue at point of rupture The points of unusual interest in the case are the cause of the rupture, and its location at the fundus uteri

Dr EDWIN RICKETTS of Cincinnati Ohio, read a paper entitled

PORRO'S OPERATION AT OR NEAR THE FIFTH MONTH FOR SMALL FIBROID OF CERVIX, ACCOMPANIED BY HYDRAMNIOS AND TOTAL RETENTION OF URINE

The author reported the following case and briefly commented on it

Mrs M, white, aged 26, of short stature, mother of two children of 6 and 3 years of age, with an abortion at 8 weeks early in 1895, no specific history, and a patient of Drs J B and C M Warwick, of Lucasville, Ohio Drs Warwick first saw her on Jan 10, 1896, finding that she menstruated last in the first week of November, 1895 They also found the uterus enlarged and firmly bound down in the pelvis, especially to the left, and extremely tender to pressure There was uterine hemorrhage in March, 1896, and again in the following month lasting for twenty four hours Her labors and abortion were prolonged and severe and accompanied by great suffering, while dilatation in all instances was accomplished with difficulty From Jan 10, 1896, she had no desire to urinate, nor could she void a drop of urine without the aid of the catheter Feb 23, 1896, she had severe labor pains lasting thirty six hours and accompanied by slight hemorrhage, the right portion of the cervix being soft and the left hard, which condition was also present at the time of operation During April and until May 22, the date of operation, she was very tender over the lower part of the abdomen, and at times had a temperature above 100, with a pulse running from 90 to 100

Dr Ricketts saw her in consultation at her home April 8, 1896, when for the first time motion of the fetus was barely perceptible May 22, Drs Warwick, Kline, Sellards and Ricketts found her abdomen larger than it should be at full term, which was due to the hydramnios present There was no difficulty in moving the fetus freely in the abdominal cavity, so thin was the uterine wall It was considered unwise to delay surgical interference, and a Porro was therefore performed under as strict asepsis as the circumstances would permit

After the abdomen was opened, Dr Ricketts passed his hand down into the pelvis breaking up the pelvic adhesions Upon the delivery of the fundus of the impregnated uterus through the abdominal incision, a rubber ligature was thrown around it low down and tight enough to control any hemorrhage which might occur The fluid which escaped upon opening the uterus surpassed in amount any he had seen delivered per viam naturalem After carefully sponging the parts, the wire was tightly adjusted below the rubber ligature by means of the Koeberle clamp, and the rubber ligature then removed After the delivery of the placenta, the fundus was amputated, leaving the ovaries and tubes intact The abdominal wound was closed with silk worm gut sutures, without stitching any tissue to the stump below the wire No drainage tube was used The extra peritoneal part of the stump was dressed with gauze, moistened in glycerin and tincture of iron, the stump being held up by the double hooded pin of Tait The placenta and fetus were small for near five months gestation, and the cord was tied in almost a hard knot, harder than any he had seen The fetus had marked cyanosis and gasped but once Recovery of the mother was satisfactory

TREATMENT OF PUERPERAL INFECTION

Dr H W LONGYEAR of Detroit, read a paper on this subject He first spoke of the prophylaxis and under this head of the difficulty of securing reliable statistics regarding puerperal mortality of patients under the care of midwives in this country The prophylaxis was divided into general and specific He spoke of the treatment of infection from abortion and from childbirth at full term, and presented an instrument for use in removing the remains of secundines from the uterus, designed by him He also exhibited a self retaining drainage tube of his own invention and demonstrated its applicability He reported two cases of puerperal infection treated successfully by the use of diphtheria antitoxin serum He condemned the performing of hysterectomy for puerperal septicemia except in very exceptional cases

The American Public Health Association

[Special Correspondence of the JOURNAL]

The Twenty fourth Annual Meeting of the American Public Health Association held at Buffalo N Y, Sept 15-18, 1896

(Continued from page 766)

WEDNESDAY—MORNING SESSION

After the customary announcements by the chairman of the Local Committee of Arrangements, the daily report of the Executive Committee was made by the Secretary presenting the names of forty additional applicants recommended for membership, who were thereupon elected

The roll of the Advisory Council, which consists of one member from each State, Territory, the District of Columbia, the Army, Navy and Marine Hospital Service of the United States, the Dominion of Canada and each of the Provinces, and from each state, territory and the Federal District of the Republic of Mexico, eighty one in all, was then called and vacancies filled by the President

The scientific work of the day began with the reading of the Report of the Committee on Disposal of Garbage and Refuse by the chairman, RUDOLPH HERING, C E of the City of New York The elaborate nature of this admirable exhaustive report precludes any epitome giving a correct idea of the subjects of inquiry Cities were considered in three classes 1, the large, those over 100,000 population, 2, the medium, those numbering between 40,000 and 100,000, and 3, the small those under 40,000—and the various methods of disposing of garbarge in each, whether by cremation, by filling in and ploughing into the land, by dumping into the sea, lakes or rivers, or by being fed to animals, were considered with reference to cost and satisfactory results The cost ranged from 75 cents to 2 cents per capita, according to population and the method of disposal The reduction process in use in about ten cities varied from 15 to 67 cents per capita Regarding cremation, the expense was, in large cities from 2 to 6 cents, medium cities 6 to 10, and in one small city 20 cents During the past year, contracts have been made for the introduction of crematories and one reduction plant in New York City, at a cost of $90,000 or 6 cents per capita The committee have been awaiting final results from experiments in Berlin and Hamburg before arriving at definite conclusions, and, therefore, asks to be continued

Papers followed on the "Disposal of the Garbage and Waste in the Household" by Colonel William F Morse of the city of New York, another entitled "A Plea for the Domestic Disposal of Garbage," by Dr N E Wordin of Bridgeport, Conn, member of the State Board of Health of Connecticut, and on "The Disposal of Household Garbage and Excrement," by Major William S Tremaine, of the Medical Department of the U S Army (retired) They were all based on the drying, cleaning or combustion of waste by the kitchen range or attachments to the stovepipe This group of papers elicited a very lively discussion, participants being limited rigidly to five minutes Dr Gihon, U S Navy, began by suggesting the proper way of disposing of at least one half the garbage was to eat it instead of throwing it into the "swill pail," and instanced the custom in France and Switzerland of making palatable dishes of surplus food as a wiser and more economic course than throwing it away Surgeon General Sternberg, U S Army, spoke of the necessity for the prompt disposal of garbage, because of the danger of dissemination of putrescent matter by house flies Many mysterious cases of diarrhea and typhoid fever are due to direct contamination of flies, and cases of cholera have been caused in the same way Dr Clark agreed with Dr Gihon that the American people cooked more food than they can eat and consequently wasted it Dr Lee introduced Dr Varian, President of the Health Board of Titusville, Penn, who described the method of burning garbage in that city, where natural gas is the only fuel Dr Carter of Detroit, said if the fluid part of garbage is poured off, all the rest can be burned in the ordinary fire box Dr Mitchell objected to the endorsement of Major Tremaine s proposal to cremate excrement, as this had been known to produce typhoid contamination Dr Durgin of Boston, said that of the two kinds of waste material that collected out doors and that in the house, the latter must go through fire to be purified He advocated plants situated at various sites in the city to have as short a haul as possible and he did not think the duty of removing household garbage should be imposed on the city Dr Howe of Buffalo, referred to flies as filth disseminators He said that if people were required to pay for the removal of garbage as they do for their gas, they would not make so much Dr Daniel Lewis, President of the State Board of Health of New York, advocated curative stations every few blocks for the removal of garbage instead of casting it over the whole city Dr A N Bell of Brooklyn insisted on the necessity of compelling citizens to dispose of their garbage in their own homes and at their own expense

The report of the committee on "The Transportation and Disposal of the Dead" was read by the chairman, Dr Charles O Probst, Secretary of the State Board of Health of Ohio, and was following by a paper on the "Quick or the Dead" by Dr Benjamin Lee, Secretary of the State Board of Health of Pennsylvania, in which the claims of living over the dead were set forth Dr Durgin of Massachusetts, recommended a steel casket for deceased bodies and Dr Smart U S Army, spoke of the contamination of the soil of cemeteries from dead bodies

AFTERNOON SESSION

A paper on "Measures for the Prevention of Blindness," was read by Dr Augustin Chacon, vice president of the Ophthalmologic Society of Mexico, and delegate from the State of Aguascalientes Mexico

Dr Lucien Howe of Buffalo, said that a large proportion of the diseases inducing blindness is preventable, but only preventable when attended to early, and they are not attended to early because the persons who have them in charge are apt to say that they amount to nothing and the cornea is ulcerated through before they become subjects of treatment The law ought to require every case of infantile ophthalmia to be reported at once to some legally qualified practitioner This is done in some States, but in others, as North Carolina, it was found it could not be passed because it affected midwives He offered two resolutions on the subject which were referred to the executive committee Dr Valentine spoke on the same subject, advocating Credé's method of prophylaxis

A paper on "Miasmatic Fevers in the State of Sonora,' by Dr Alberto G Nonega, delegate from the State of Sonora Mexico, and one entitled a "Summary of Sanitary Legislation in the State of Mexico," by Dr Maximiliano Alvarez, delegate from that State, were read and followed by the Report of the Chairman of the Committee on National Health Legislation, Dr Henry P Walcott, president of the State Board of Health of Massachusetts, which was read by Dr Wingate of Milwaukee, a member of the committee

The proceedings were at this point interrupted to permit the introduction and customary reference to the Executive Committee of resolutions offered by Dr Coventry of Windsor, Ont, declaring as the sense of the Association that boards of health should be absolutely independent of political considerations influencing their appointment or conduct, and by Surgeon General George M Sternberg, authorizing the secretary to receive subscriptions for a monument in the city of Paris to Pasteur, which brought Medical Director Albert L Gihon, U S Navy, who is chairman of the Rush Monument Committee, to his feet, with an amendment substituting the City of Washington for Paris, and the name of Benjamin Rush for that of Pasteur

Papers entitled 'Obiter Dicta Concerning Sanitary Organization," by Dr A Walter Suiter of Herkimer, N Y, "Some Thoughts Relative to National Health Legislation," by Dr U O B Wingate of Wisconsin, and "On the Sanitary Administration of Unincorporated Districts," by Dr Henry Mitchell of Trenton, N J, were then successively read by their authors Dr Mitchell proposed that the sanitary authority in each township should be exercised by one individual, that each local officer should hold office for five years, that examinations of candidates for appointment should be by State boards of health, and appointments only made from a list of persons recommended by the State boards, that removals should be made only for cause, and that the local health officer should be paid by the governing body for his services

Dr C E Holgate of New Haven, said, that laws covering these points had already been enacted in Connecticut, and Dr Caverly of Vermont, added that State to the list of those having a county organization of health officers Dr Jones of Greenwich, Conn, recommended the establishment of a College of Preventive Medicine Dr Bryce of Toronto, spoke in behalf of the measures recommended by the committee Dr Lee of Philadelphia, explained the reasons for the delay in sanitary organizations in Pennsylvania Dr Carter of Des Moines, said that there were three thousand local health boards in Iowa with as many physicians as health officers These are all subordinate to the State board of health and he believed that all State boards should be similarly subject to a National board of health Dr Daniel Lewis of New York, was of opinion that the committee should be one of investigation and not one to make recommendations and he doubted whether a resolution could be passed in this Association in favor of a controlling National board of health Dr Mitchell submitted a resolution on the subject of his paper, which went to the executive committee

The report of the "International Committee on the Prevention of the Spread of Yellow Fever" was then read by the chairman, Dr Felix Formento of New Orleans, followed by a paper entitled "Contribution to the Study of Yellow Fever from a Medico geographic Point of View,' by Dr Eduardo Liceago, president of the Association and a second "Contribution to the Study of Yellow Fever Epidemic in Cordoba," by Dr Gregorio Mendizabal, delegate from the State of Vera Cruz Dr Formento's resolution recommending a memorial from the President of the United States to the Spanish American countries which are permanent foci of yellow fever, was referred to the executive committee

It had been the intention to hold no evening session but the desire to hear the paper ' On Isolation Hospitals" by Dr John L Leal of Paterson N J, was so great that a recess was taken until 8 P M, when it was read and discussed by Dr Lindsley of New Haven, Dr McShane of Baltimore, who exhibited plans of the new isolation hospital of that city, Dr Barnes of Boston, Dr Plunkett of Nashville, Dr Wright of New Haven, Dr Probst of Columbus, Ohio, Dr Woodward of Washington, D C, Dr Hibberd of Richmond, Ind Dr Gihon of U S Navy, Dr Durgin of Boston and Dr Woodhull of U S Army, the Association adjourning at 10 P M, to attend a reception by the Ellicott Club

The Mexican delegates celebrated the eighty sixth anniversary of the Declaration of Independence of the Republic of Mexico (Sept 16, 1810) by a banquet at the Iroquois Hotel, and later joined their fellow American and Canadian members at the reception at the Ellicott Club

Thursday—Morning Session

The meeting having been promptly called to order by the First Vice President, Dr Woodhull the daily announcements of the Local Committee of Arrangements was made by Dr Lucien Howe of Buffalo, and the Treasurer Dr Henry D Holten of Brattleboro, Vt, presented his annual report which was referred to the Auditing Committee

The funds on hand Sept 23 1895 amounted to	$ 74 [illegible]
Received from sale of Transactions	11 40
Received from membership dues	207 60
Received from advertisement in volume	118 00
	$[illegible] 48

Expenditures for reporting proceedings, publication of volume, expenses of Secretary and Treasurer's offices expressage, postage and printing of early volumes of Transactions to complete sets, amounted to	$1,522 96
Leaving a balance in the treasury of	$1,362 92
The unexpended balance of the "index fund," for indexing the early volumes is	$493 48

The Secretary reported from the Executive Committee, with its recommendation of passage, the following resolutions, which had been referred to it

1 That the Treasurer be authorized to appoint an assistant treasurer for Mexico

2 The resolution of Dr Smart, U S Army, to appoint a special committee of five members to consider and report upon some method by which international arrangements may be effected to prevent the transmission of infectious diseases from one country to another

3 The resolution of Dr Coventry of Canada, amended to read, that the Association views with pleasure the growing tendency of many States and Provinces not to manage and control the bureaus of public health by political partisans, and not to exclude from office sanitarians who may differ politically from the party temporarily in power From a scientific standpoint, as well as in the best interests of public health, we welcome this tendency and take this opportunity to place our selves on record by declaring that it is conducive of the best interests of public health to ignore political lines in the formation of State, Provincial and other boards of health, and that a copy of this resolution be sent to the Secretaries of State of all Federal, State and Provincial governments of the countries represented in this Association

4 The resolution of Dr Wingate of Wisconsin, amended to read, that it is the sense of this Association that the Committee on National Health Legislation be continued and that efforts be continued to influence the Congress of the United States to establish a Department of Public Health at Washington, D C

5 The resolution of Dr Liceaga of Mexico to constitute a special committee of five to study the periods during which each contagious disease is transmissible and the term during which any person, who has suffered from such disease, is dangerous to the community

6 The resolution of Dr Howe of Buffalo—"Whereas, about one fifth of all the inmates of schools and asylums for the blind are there because of having suffered from purulent ophthalmia in infancy, and whereas, the ravages of this disease can be controlled in almost every case if proper treatment is begun promptly, and whereas, most of this blindness is due to the wilful or ignorant neglect of nurses and midwives, thus causing unspeakable misery to the innocent victims and great yearly cost to the State treasury,

"*Resolved*, That this Association heartily approves of the laws already enacted in several States which compel midwives and nurses to report these cases, under heavy penalty immediately to legally qualified practitioners or to proper officers of local boards of health, and *Resolved*, That this Association recommends and urges the adoption of similar laws in other States of the Union or elsewhere wherever practicable "

All which were unanimously adopted

The Secretary reported the names of twenty five additional applicants for membership recommended for election and who were accordingly elected, after which the scientific work of the Association was begun and continued in the following order Report of committee on "Pollution of Water Supplies," by Major Charles Smart, Washington, D C, Chairman, report of committee on "River Conservancy Boards of Supervision," by Dr Peter H Bryce of Toronto, Secretary of the Provincial Board of Ontario, Chairman, report of committee on "Protective Inoculations in Infectious Diseases," by Dr Charles N Hewitt of Red Wing, Minnesota, Secretary of the State Board of Health of Minnesota, Chairman

At this point Vice president Woodhull interrupted the proceedings to read a telegram just received from the medical attendants upon the Second Vice president, Dr Henry Sewall of Denver, Colorado who was prevented from being present by a serious attack of typhoid fever The telegram was in reply to one of sympathy sent by the Association on Tuesday upon motion of Dr Montizambert of Canada and informed the Association that his case was progressing favorably and thanking it for the interest expressed

A paper on "The Serum Diagnosis Test for Typhoid Fever," by Dr Wyatt Johnston of Montreal, presented a modification of the serum diagnosis test introduced by Vidal, which Dr Johnston had found expeditious and satisfactory A paper on the "Prophylaxis of Typhoid Fever," was read by Dr J Eliot Woodbridge of Cleveland, Ohio, who stated that the flow of the lake front of the city, which was originally clear white sand over a sub stratum of clay, had in the course of recent years been covered by a progressively increasing layer of slime several feet thick He declared that for every case of typhoid a city government is morally responsible, as all cases can be traced to bad sewerage or polluted water The paper was discussed by Drs Carmona y Valle of Mexico, Cerna of Texas, Kinyoun of U S M H S, Learned of Massachusetts, and Bailey of Kentucky

Dr Durgin of Boston, offered a resolution deploring the passage by Congress of a law preventing experiments upon animals, which was referred to the executive committee

The next series of papers excited the greatest interest and elicited discussions and inquiries propounded by members to the authors "Practical use of Formic Aldehyde as a Disinfectant," by Prof Franklin C Robinson of Maine, "A Convenient Lamp for Generating Formaldehyd Gas," by Dr A E DeSchweinitz, Washington, D C, "Preliminary Note on the use of Formaldehyd for Room and Car Disinfection," by Surgeon J J Kinyoun of Washington, D C

AFTERNOON SESSION

Report of committee on the "Cause and Prevention of Diphtheria" was presented by Dr J J Kinyoun, of Washington, D C This was followed by papers on "Diphtheria in Chihuahua," by Dr Miguel Marquez, of the State of Chihuahua, Mexico, "On Bacteriologic Diagnosis as governing the admission and discharge of patients in Diphtheria Hospitals," by Professor E B Shuttleworth, of Toronto "On Prophylaxis of Paludism," by Dr Alfonso Ruiz Erdozain of Hidalgo, Mexico, "Paludism in the State of Morelos and its prophylaxis by Sanitary Measures," by Dr Angel Gavino, of the State of Morelos, Mexico, "Brief Notes on Public Hygiene in the State of Tamaulipas," by Dr G Garza, of Laredo, Mexico, "On Public Health in Tabasco, Mexico," by Dr Juan Muldson, of Tabasco, Mexico, "On Sanitation in Hospitals for the Insane," by Dr George H Rohe of Maryland, "Should Measles be Quarantined? by Dr Henry M Bracken, of Minnesota, report of committee on "Causes and Prevention of Infant Mortality," by Professor Charles N Hewitt, of Minnesota, "On Mortality of Infants, the Causes and Means of Diminishing it," by Dr Salvador Garciadiego, of Jalisco, Mexico, "On Diarrhea of Children," by Dr Jose M Benitez, of Guadalajara, Mexico

EVENING SESSION

Session began with the report of committee on the "Use of Alcoholic Drinks from a Sanitary Standpoint," by Dr Felix Formento of Louisiana The committee favored the moderate use of pure wines and beer, and advocated temperance and not prohibition A sharp distinction was drawn between such use and alcoholism from the abuse of ardent spirits "Spasmodic and inefficient Sunday laws" were decried and the palm for hard drinking awarded to Americans as a nation Wine producing and wine and beer drinking countries were cited as comparatively free from intoxication Coffee drinkers, according to the committee, are seldom addicted to the immoderate use of liquor

The paper was discussed pro and con by Drs Carter, Grosvenor, Bailey, Vice president Woodhull and Nelson R Hopkins

A paper was read "On the Bicycle in its Sanitary Aspects," by Dr Albert L Gihon The speaker announced that he had not set out to assail the bicycle and its ideal rider, but only the hideously distorted creature whose unnatural posture is affected by "expert" wheelmen He adverted to the serious harm to women from improper saddles, quoting from medical wheelmen in support of his statements As a mere matter of health incentive he said, pedestrianism remains unrivaled, but for those who will not walk the bicycle under the restrictions and limitations indicated may become an useful alternative If the bicycle is to merit praise, the ridiculous posture affected by professional male riders and their imitators must be discountenanced and denounced by wheelmen's periodicals, forbidden by wheelmen's clubs and discouraged by reputable makers and dealers Girls under the age of puberty should be restricted by parents, guardians and teachers to short rides, and no woman of any age be mounted on any other than a wide elastic seat without anterior horn or central ridge Lastly, the gate of the bicyclist should be such as can be maintained with the least personal exertion The paper was briefly discussed by Dr Carter and Dr Mosher of Ann Arbor, Mich

This was followed by a paper "On the Part that Public Instruction Should Have in the Way of Precaution Against Contagious Diseases, by Dr Carlos Santa Maria of Durango, Mexico, "On Public Bathing Establishments, with a Description of the New Public Bath in Brookline, Mass," by Dr H Lincoln Chase, "On Public Baths" (illustrated by stereopticon), by Dr W H Tolman of the city of New York

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE INCLUDING POSTAGE
Per Annum, in Advance $5 00
Single Copies 10 Cents
Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 61 Market Street (Occidental Buildings) Chicago, Illinois

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association Dr Henry P Newman Venetian Building, Chicago, Ill, sending him a certificate or statement that the applicant is in good standing in his own Society signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL *of the Association will be forwarded regularly*

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL *office*

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL, proof sheets returned or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION 61 Market Street (Occidental Buildings) Chicago

Original communications are only received with the understanding *that they are exclusively contributed to this* JOURNAL

INFORMATION WANTED

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL as we have been notified by the postmasters of the larger cities that second class mail matter not having street address, would be placed in the general delivery *to await call*

SATURDAY, OCTOBER 10, 1896

THE AMERICAN PUBLIC HEALTH ASSOCIATION

The mere enumeration of the reports of special committees and individual papers read at the recent meeting of the American Public Health Association at Buffalo, N Y (September 15-18), is sufficient evidence of the amount of scientific sanitary inquiry accomplished Four addresses, sixteen reports of committees and fifty-three papers—seventy-three in all—constitute a formidable list, and when to these are added the discussions on these reports and papers, which are arranged in groups according to subjects, these discussions being a characteristic of this body, which it encourages and on which it justly prides itself, its reputation as a working body can not be questioned The Association was actually in session eight hours on the first day, eight on the second, nine on the third and five on the fourth, a total of thirty, the general business occupying scarcely an hour each day Giving thirty minutes to each report and limiting voluntary papers to twenty, of which only five were read by title, and restricting discussions to five minutes, it will be seen how well the time was filled, a result accomplished only by the admirable business methods of this excellent body The unflagging interest of the old members was shown by the fact that nine of the thirteen surviving ex-presidents were in attendance and very actively engaged on duty as members of the Executive Committee Prof STEPHEN SMITH of New York City, the founder of the Association and its first President (1872, '73 and '74) in his address in acknowledgement of his enthusiastic welcome at Buffalo declared he was especially gratified at discovering that the Association still adhered to its early practice of doing its administrative business through an executive committee, thus taking the disputations and hysteric jangling, by which so much time is wasted in many large associations, off the floor and permitting the legitimate work for which the Association was organized to be performed Every resolution offered is read and upon being seconded referred without debate to the Executive Committee, by which it is carefully considered, amended, if thought best in substance or language, and referred back the following day to be put upon its passage, or quietly tabled in committee The confidence in the conclusions of the committee is such that debate seldom occurs and dissent rarely The composition of the committee justifies this confidence The five officers, six elected members, of whom three are renewed annually, and the ex-presidents secure a judiciary of old and experienced members Occasionally some disappointed proposer of a resolution, on finding his hobby not reported, jumps up with an amendment to the constitution changing the composition of the committee usually by leaving out the ex-presidents, but a year of sober reflection before the retaliating amendment can be considered, has heretofore saved the Association the loss of what may be considered its balance wheel The participation of the former presidents preserves a constant policy and preserves it from local influences, log-rolling and hasty, injudicious legislation

The duty of the Executive Committee is no sinecure It assembles early on the day preceding the annual meeting and is in session the greater part of that day and subsequently daily from 8 or 9 to 10 A M, and usually at night after the adjournment of the evening general session, often when matters of importance have been referred to it continuing its work until two or three o'clock in the morning The Executive Committee investigates every application for membership and determines whether to recommend the applicant for election As stated, it considers every resolution introduced into the Association, amending it as it may believe proper, or changing its phraseology It examines all papers and prepares the daily programs, and generally discharges all the working duties of the Association An Advisory Council, consisting of one member from each State, Territory, the District of Columbia, the Army and Navy of the United States the Marine-Hospital Service, the Dominion of Canada and each of the Provinces, and each State, Territory and the Federal District of the Republic of Mexico, besides acting as a nominating committee of officers and selecting the place of meeting for the ensuing year, also considers important questions of policy and makes such recommendations to the Association as shall best secure its objects Through this council, which is virtually a senate of over [illegible] members, the equal representation of all the constituent nationalities and States is obtained, and its recommendations in matters of vital importance have always been sustained At the meeting just ended however, its selection of the place of meeting for 1897 was reversed for reasons that had not been presented to it

The Executive Committee, the Advisory Council and the Publication Committee (the last consisting of the Secretary and and two members residing conveniently near him), are the three standing committees, and practically do all the general business, and the splendid uniform series of volumes of its transactions for the twenty-four years of its existence are speaking testimony of the value of its sanitary work, constituting a hygienic library containing information which FLORENCE NIGHTINGALE declared could not be found anywhere in Europe To the Chairman of the Publication Committee, the Secretary of the Association, Dr IRVING A WATSON of Concord, N H, Secretary of the State Board of Health of New Hampshire, now in his fifteenth year of office, is due the invariably neat and appropriate announcements, circulars, etc, which are characteristic of this body Indeed, Dr WATSON's suggestion of a desire to resign the Secretaryship (which is a triennial office), on account of the proportions its duties have assumed, alarmed the members at the prospect of losing an officer so exceptionally qualified, faithful and efficient

The American Public Health Association is characteristically *American* In 1884 it extended its membership to Canada and in 1890 to Mexico, the membership of both these countries embracing their most distinguished sanitarians and health officers, who have been as regular in attendance, as interested in the work, and as enthusiastic and able contributors as those from the United States Two annual meetings have been held in Canada, in 1886 and 1894, and that of 1892 in Mexico, and both Ottawa and Toronto contended for the meeting in 1897

An especially commendable feature of this Association is that it is in no sense a junketing body It goes where it hopes to do good and devotes itself to that end It asks no courtesies and is prepared to assume all the expenses of its meetings Nevertheless, civilities have been everywhere generously showered upon it and accepted conditional upon their non-interference with its legitimate work At Buffalo the Local Committee arranged its excursions after the formal adjournment, only requesting that one night might be assigned for a reception at the Ellicott Club, but an interesting paper induced the members to meet before the reception and hold a session of a couple of hours before presenting themselves at their hosts'

The system of special committees, covering almost the whole ground of public hygiene, secures a concert of inquiry At Buffalo, sixteen of the seventeen special committees (now numbering twenty) actually presented reports, and an examination of the authorship of these reports and of the individual contributions, shows that all but five or six of the seventy-three writers hold or have held responsible representative positions as members of State and Provincial Boards of Health and of the Superior (National) Board of Health of Mexico, as health officers of cities, and as *Government officials* of the United States Army and Navy and the Department of Agriculture, thus directing their several lines of inquiry in common channels Dr STEPHEN SMITH claims for the Association the credit of having developed the system of State and Provincial Boards of Health into its proportions Originally the subject of a special committee, whose work grew so large that a whole session was devoted to it exclusively, becoming later a Conference of State Boards of Health, meeting at first coincidently with the Association and later independently, the new organization has never lost interest in the parent body, as shown by the numbers of presidents, secretaries and members of State and Provincial Boards of Health who participated in both the business and sanitary work of the late meeting as chairmen and reporters of special committees, authors of papers and disputants in the discussions Perhaps the crowning glory of the American Public Health Association has been the establishment of a fraternal union of the United States, Canada and Mexico in one body, in which international distinctions are abolished, and the sanitary officials of the three countries harmonized in the interests of a common humanity in a mutual policy of protection against epidemic *importations*

A SLANDER ON THE MEDICAL PROFESSION

In a medico-legal congress a year or two ago it was asserted that it was the practice of reputable physicians to deliberately shorten life in cases of painful and incurable disease A large portion of the public undoubtedly accepted this statement as gospel truth and possibly thought it nothing extraordinary The superstition that the orthodox treatment of human rabies is of this character is held by many of the ignorant in the community, and even grosser errors of the same general nature may be occasionally met with among them

The lawyer who made the statement referred to, defended and advocated the practice and his utterance was, without question, based on no knowledge but was offered as a part or support of the argument he was making before the congress It is a pity his ideas of the ethics of another learned profession should have been so hazy, and also that he was not more scrupulous as to his facts His ideas were noticed to some extent by the medical and secular press at the time, the public had at least a chance to be enlightened and it is probable that, on the whole, the utterances did little harm

The notion, however, that incurable diseases should be cut short by an expeditious euthanasia is every little while advanced by some one-sided humanitarian. The latest comes from California, where a misguided clergyman offers an elaborate proposition of a law for the doing away with the victims of incurable disease. It provides that "a commission of eight persons of high character and unassailable reputation be appointed by the governor of the State, four to be physicians, and the others to be the district attorney, the chairman of the health board, and two public spirited citizens of pronounced humane tendencies. The sufferer should appeal to the commission with the consent of his family, then the case should be thoroughly investigated by the commission, and if the physicians are satisfied that every known remedy has been tried, and the case is absolutely incurable and the patient has suffered intolerable pain, and the relatives can show that they act from none but humane motives, and all these points have been settled to the satisfaction of the commission, it should be empowered gently and humanely to put an end to the misery of the affected person."

The above in its elaborate legal ordering of homicide is very reminiscent of an imaginative work of fiction by an English writer of note that appeared some ten or fifteen years back, and, like it, might be taken as a satire on certain extreme social and economic tendencies. The author of the present proposal, however, is accepted as in earnest, and is probably only one of a large number who in their ill-regulated philanthropy throw well known moral and social principles to the winds. It is easy to see to what consequences his line of reasoning would lead, if the idea of the sacredness of human life were abolished, as would be necessarily the case with the adoption of any such plan.

The medical profession owes to itself and to the public a duty in this matter. It is not that it is misunderstood and misrepresented, there are many respectable and even estimable people who are more or less demoralized by the publication of such propositions, and public sentiment, which ought to be on the highest plane, is degraded to a very material extent by them. Society needs all the safeguards it possesses and the belief in the absolute inviolability of human life is one of the most important of these. There is no need, of course, to say that regular physicians should not encourage any belief in popular impressions derived from such publications, but there may be a very positive utility in their actively denouncing them. At all events they should endeavor to correct any popular belief that our profession sanctions even the suggestion of the violation of human or moral laws. It ought to be unnecessary to say that this should be done, but if we grow familiar with such charges and consequently neglect or ignore them, we have no assurance that such neglect will not appear to the uninformed as a tacit acknowledgment of their truth. When clergymen make such propositions as the one here reported what wonder that a credulous public should think it possible that doctors might be ready to endorse them or carry them out. The commandment "Thou shall not kill," would seem to be binding even upon the clergy. The public knows little and misunderstands a great deal in regard to the ethics of our profession and it is not amiss therefore to occasionally correct a possible misapprehension that they are not in all respects strictly in accord with the highest ethical standards. There is little danger, judging from our past, that we will protest too much.

THE MANIA FOR PROPER NAMES.

Several of our foreign exchanges are protesting against the practice of rendering the study of anatomy more difficult by encumbering the text books with the names of parts of the body which neither describe nor locate them, but merely commemorate the name of some obscure anatomist. The boast of the student now is that he can quote more proper names than the rest, but they are of no benefit to him in locating the parts designated by them. How much better to call it the anterior sacro-dural ligament than Trolard's ligament, for instance? It is a longer name but it means something, and enables the student to place it at once.

In surgery the abuse passes all proper limit. It is not only perplexing to enumerate the various operations, but in many cases a name has been hastily applied to an operation not devised by the person named. It is simply an impossible thing for the average surgeon to mention *seriatim* the various incisions that have had proper names tacked on to them, and then the question of priority is generally impossible to settle by any amount of research. One of our recent dictionaries has devoted much space to the definition of operations catalogued under proper names, and as for instruments, many of them have two or three claimants. The familiar example of a cranial saw first figured in the "Chyrurgeons Storehouse" of SCULTETUS, coming to us for a long time under the name of HEY's saw, and by many still called by that name, affords ample evidence if any more were needed, of the loose practice in this matter.

In medicine there has been a singular passion for naming diseases for some favorite, or somebody who is presumed to have been the first to give a description of the disease. In some cases we have conflicting claims of priority, but the number grows with too great rapidity, and in these days of almost total neglect of the history of medicine, serious and absurd errors are perpetuated. Now let us keep close nature in our nomenclature, and have it as nearly descriptive of the thing itself as possible Then we approach the true scientific ideal

CORRESPONDENCE

Medical Education

MONTCLAIR, N J , Sept 26, 1896

To the Editor —The two editorials upon medical education in the last issue of the JOURNAL are exceedingly well considered and show a decided disposition to go to the root of things What is particularly pleasing in your remarks is the strong demand for *thoroughness* in our medical schools, and the intimation that until better methods of teaching are adopted the mere lengthening of the curriculum will avail little The medical schools seem disposed to indulge in much self congratulation because a number of them have extended the period of study required for a degree of doctor of medicine to four years, and most of them now seem to require more or less preliminary education In the latter direction it hardly seems possible that they can go too far But the rigid requirement of four years study of medicine is perhaps not so wise a measure At all events it has always seemed to me that the object to be gained in going to a medical school is a knowledge of medicine sufficient to enable a man to enter upon the practice of it, and some men will easily acquire in three years what it will take others four to accomplish No two minds are precisely alike in childhood and as individuals approach maturity these mental differences increase rather than diminish so that it may prove a hardship and an injustice to a man with an unusually brilliant and acquisitive mind to be forced to spend the same amount of time in studying for his degree as the more slow going individual Your editorial speaks of bedside examinations of students In like manner the candidate should be examined in the deadhouse as to his knowledge of gross pathology, should operate upon the cadaver (if living subjects are not available), should bandage the manikin, etc He should compound prescriptions, and be required to detect and demonstrate incompatables and poisons and should give the antidotes to the latter, in short he should be put through an examination which would really reveal what he knows

No written examination, no oral examination, no bedside examination, nor even the certificate of good moral character, alone is a sufficient test of a man's capacity to enter into practice But a judicious combination of them all is, I submit, necessary and should be adopted in each case Let the examinations last from three to six days The examining board should sit constantly or nearly so and the candidate should be allowed to appear before it whenever he chooses Let a fee sufficient to pay the board's expenses, say from $50 to $100, be charged each candidate If he only desires to take part of the examinations, there seems to be no reason why he should not do so, paying only the fees of those examiners before whom he chooses to appear

One student might qualify himself to pass all these examinations in two or three years Another, who would perhaps make a sober and more reliable practitioner, would require four or five years And—and this is the most satisfying part of the plan—a dullard, a superficial or lazy student, or one whose preliminary education had been quite defective could never pass at all What a glorious day it would be for American medicine if such a plan could only be realized ! How such a body of trained examiners would sift out the weak and badly prepared candidates ! No amount of cramming would enable a weak or illy prepared man to pass a competent and trained examiner, who could take the applicant to the bedside, to the operating room, to the laboratory and to the dead house, who would require one or more carefully written papers upon his particular subject, and any number of answers both oral and written that he might think proper

Such an examination as the one outlined used to be required and I presume still is by the Army Examining Board When this board had finished five or six days' examination of a candidate, both the board and the candidate felt that the latter had told all he knew It was the only fair and satisfactory medical examination which I ever passed My examinations for my degree were trivial, almost foolish, and my examinations for the hospital were too short and were *greatly a matter of luck*

It has been asserted over and over again that an examination does not show what a man knows, and this allegation is measurably true of such examinations as I have last spoken of, depending for their result as they do upon so many fortuitous circumstances, as, *e g* , the readiness and assurance of the candidate in case of oral examinations, and his capacity for cramming in case of written examinations But an examination that takes plenty of time and which attacks the candidate's fund of knowledge in various ways as, for instance, setting the ready and superficial man to write answers which require thought, accuracy and careful study, and on the other hand, asking the slow, methodical man, whose written answers may be good, such questions orally as to reveal whether his work has covered sufficient ground, or taking the bookish man to the bedside or the laboratory and letting him show whether he can put his theories into practice, etc

If the medical schools, the AMERICAN MEDICAL ASSOCIATION, the New York Academy of Medicine and every representative body of physicians and the profession at large will unite in insisting upon competent boards of examiners in medicine (whether they be State or National) we may sometime get such bodies of examiners and such examinations that the degree of doctor of medicine shall of itself confer distinguished honor Our medical schools and our physicians would in that case no longer be looked down upon by our foreign confrères The greatest good for the greatest number would be attained because the average physician would be a man of sound education and broadened views This state of affairs would perhaps be rather near the millenium, but it is really not entirely beyond the range of possibility Very respectfully yours,

RICHARD C NEWTON, M D

Expert Medical Testimony

PHILADELPHIA, Sept 28, 1896

To the Editor —There have been many papers and articles written on the subject of expert testimony but none I think so clearly express what is needed in courts as that published in our JOURNAL of Sept 26, by L Harrison Mettler of Chicago, under the title of "Insanity in Court "

The Doctor's arguments are so convincing that criticism is well nigh disarmed His demand for a separate medical trial to precede the civil where a plea of insanity is offered, carries great weight and would seem to be perfectly fair

The commission, suggested by him, to be composed of learned and experienced experts appointed by the supreme court or in other constitutional way beyond the reach of politics is certainly to be desired

It is only too true that "the present system does not carry out the abstract spirit of the law that every man shall be tried by his peers, but on the other hand works injustice in many cases of real insanity and favors the exercise on the part of criminals of feigned insanity " Such being the case, is it not time that the great AMERICAN MEDICAL ASSOCIATION should assert itself and formulate and pass resolutions in accordance with the progressive ideas on the subject of expert testimony

Yours very truly, T RIDGWAY BARKER, M D

PUBLIC HEALTH

Smallpox at Marseilles.—Since 1872 there have only been eight years when the deaths from smallpox at Marseilles have been less than a hundred, and in 1886 they were over 2,000. There have already been 358 deaths in the first quarter of 1896, and the lax preventive measures render the city a menace to the rest of Europe. The disease is practically endemic in the Italian colonies there, which contain about 100,000 souls, with thirty or forty families crowded into buildings that would scarcely accommodate ten properly.

Oil in Urinals.—It has been found that if urinals are coated with heavy oil, the urine leaves no traces nor odor as it runs off. The 178 public urinals of Vienna are treated in this way, with satisfactory results, saving the city $30 a year for the water supply of each. Many other European cities have already adopted the use of oil for this purpose. The urinal is scrubbed with a broom and plenty of water once a week or fortnight. When it is quite dry it is painted with thick mineral oil, obtained by distilling petroleum. Another system has a permanent syphon supply of oil.—*Journal d'Hygiène*, September 30.

Successful Retrovaccination.—The New York Health Board, after a long series of experiments, has solved the problem of retrovaccination, the vaccination of calves with matter taken from vesicles on children. Early attempts in this direction gave imperfect results on account of the choice of improper kinds and methods of collection from the children. A report submitted by John H. Huddleston, Medical Inspector, shows that complete success has now been attained in the manufacture of vaccine virus. In all fifty calves have been inoculated with the virus taken from children. In forty-seven of these the results of the clinical test of the virus thus produced are known. The test consists in vaccinating three places on each of five previously vaccinated children. With the virus obtained from the animals there have been vaccinated 123 children, with a total result of 367 vesicles obtained out of 369 possible. In over 300 cases vaccinated and inspected this month at the department, 95 per cent. were successful, and the 5 per cent. of failures were all revaccinations.

The Distribution of Sterilized Milk in New York and Brooklyn.—Statistics obtained at the health department show the good effects of the free distribution of sterilized milk in Brooklyn under the auspices of the Board of Health, a charitable work that was made possible through the philanthropy of Mr. Nathan Strauss. The death rate during the second week of the recent hot weather among children under five years of age was only 34.4 of the total number of deaths, which is quite a remarkable showing when it is considered that the general death rate was exceptionally high owing to the excessive heat. It is necessary to go back to the beginning of June to find a week when the death rate among children was as low as that. During the period when the heat was most intense Mr. Strauss sent over to Brooklyn about 1,500 bottles of sterilized milk a day. A large force of men was employed at the New York depots, getting the milk ready for distribution, and it was transported to Brooklyn at the expense of and with the wagons and horses of the donor.—*Boston Medical and Surgical Journal.*

Treasury Regulations Regarding Immigrants.—The *Boston Medical and Surgical Journal* states that the Treasury Department has issued an order designed to prevent the spreading of contagious disease by immigrants in other places than the port of entry. It provides that after arrival at a quarantine station of a vessel upon which there appears, or has appeared during the last voyage, a case of cholera, smallpox, typhus fever or plague, and after quarantine measures provided by regulations of the Treasury Department have been enforced and the vessel given free pratique, it is ordered that notification of the above mentioned facts be transmitted by the quarantine officer to the commissioner of immigration at the port of arrival, whose duty it shall be to transmit by mail or telegraph to the State health authorities of the several States to which immigrants from said vessel are destined, the date of departure, route, number of immigrants and the point of destination in the respective States of the immigrants from said vessel, together with the statement that said immigrants are from a vessel which has been subject to quarantine by reason of infectious disease, naming the disease. This information is furnished to State health officers for the purpose of enabling them to maintain such surveillance over the arriving immigrants as they may deem necessary.

Toxicity of Alcohols.—Austria, Switzerland and Belgium are about to, or have already, established two grams per litre as the maximum of impurities allowed in alcohols, and the latter country forbids certain substances absolutely. Professor Riche in a vigorous address before the Acad. de Med. protests against the impression produced upon the public by this and similar legislation, that it is only the adulterations that render alcohol injurious. The people should be educated that the alcohol itself, brandies, etc., are distinctly toxic, and he asserts that there should not be any government authority, tacit or official, for its use as a beverage. He adds his testimony that the spread of alcoholism in recent years is appalling, and describes the customs prevalent in Normandy, where the laboring classes, young and old, all take their coffee two or three times a day, and always with cognac. The mothers even take a bottle of this "coffee" to their little children in the crèches. At one small town the amount of pure alcohol consumed per capita is more than nineteen litres a year.—*Bulletin*, September 8.

The Abolition of British Quarantine.—The *Lancet* says that under a "Public Health Act of 1896" we have this year, will be done away with the last vestige of quarantine in the United Kingdom. The principal section of the Act is the first one, in which power is granted to the local government board to make regulations, just as they have already done for the purposes of cholera, as to the hoisting of signals by vessels having any case of infectious disease on board, as to the questions to be answered by masters, pilots and others, as to the detention of vessels and persons infected, and as to the duties of certain individuals under the regulations. The term "epidemic, endemic, or infectious disease" naturally includes yellow fever and plague, the only two diseases as to which quarantine was carried out, and since all the quarantine acts mentioned in a schedule are repealed, the only method of dealing with these two quarantinable diseases will in the future be that which has now been adopted for many years as regards cholera. In Scotland and in Ireland the local government boards of those portions of the kingdom acquire similar powers, and it may be assumed that the regulations made in the three portions of the United Kingdom will be alike in all essential respects. The Act comes into operation on November 7 of this year, and by that time new regulations will doubtless have been issued to give effect to its provisions.

Dangers of Handling Skins.—At the request of the French authorities Prof. Riche has been investigating the trade in skins to determine the dangers of handling them. He found arsenic in skins from China, Chicago, Buenos Ayres, Australia and Mexico, but he does not consider the danger from arsenic so serious as the possibility of infection from the anthrax microbes. He therefore recommends the following precaution which apply to both and have been promptly enforced in Paris, where over two million goat skins alone are handled annually in the tawing works and nearly a million in the morocco factories, the majority received from China. The [illegible] ld be opened in the open air, or at least in an open shed, the ground kept wet with plenty of water or some antiseptic The workmen *should* put on special garments closed at the neck and wrists, or at least a long buttoned blouse, with rubber gloves The face, hands, arms and neck should be washed with an antiseptic immediately afterward, and the locality carefully swept and irrigated The bales should never be carried in the arms or on the back, but always on carts or barrows, and they should be stacked in the store rooms in low piles The rooms should have openings on all sides and if there is no communication with the sewers, the refuse water should be collected in tight cisterns He also called attention to the great danger of poisoning from the orpin used in tanning, which is a mixture of sulphid of arsenic and arsenious acid This is applied with a mop, but the skins are then folded and carried by hand to the pile, which is a frequent cause of ulcerations He suggests the substitution of sulphid of sodium, which produces the same effect and would put an end to the dangerous manufacture of orpin —*Journal d'Hygiène*, September 17

On the Prevention of Ophthalmia Neonatorum —We have before us two pamphlets by Dr Wm George Sym of Edinburgh bearing upon the conditions that obtain in Scotland regarding blindness from ophthalmia neonatorum The more recent of the papers is an address read before the Medico Chirurgical Society of that city, in March, 1896 In it he has briefly sketched the various modes of treatment and prophylaxis, and emphasized the importance of cleansing the face of the child from any contamination acquired during its passage through the vagina before any lotion was applied or any bathing carried out Statistics of blindness in the latest census returns showed that there were more than five thousand alive in England and Scotland who were blind from this entirely preventable disease On comparing the statistics of blindness for England with those for Scotland it was found that in the former there were 809 blind persons per 1,000,000, in whom 1 in every 6 was "blind from birth," while in Scotland there were only 695 per 1,000,000 of the population, and of these only 1 in 7 7 was "blind from birth " Children who became blind during early infancy were classed in the census papers as "blind from birth " This marked *difference in favor* of Scotland the author attributed, in part at all events, to the very much larger proportion of births in England attended by midwives and not by regular practitioners He urged the necessity of taking the greatest care to see that all women educated as midwives or midwifery nurses should be thoroughly instructed in this matter In the event of the Midwives Bill passing and being extended to Scotland this would come to be of paramount importance Dr Sym gave an account of the legislation in force in certain countries with the view of stamping out the disease In Austria, Switzerland, eleven States of the American Union, and other countries midwives were liable to more or less severe punishment for failure to report cases that occurred in their "practice " The Ophthalmological Society's (1885) scheme for giving out to each person registering a birth a slip bearing a warning as to the danger of the disease fell through, but in Glasgow and certain other towns this had been done at the expense of the corporation, and Dr Sym urged a similar proceeding in Edinburgh Contrasting medical practice twenty or thirty years ago with that of to day, the number of cases of ophthalmia in infants was vastly less at the present time, and the cases as a rule were not so virulent

The Infectious Disease Hospitals of Berlin —The *Sanitary Journal*, June, has a special report on the fever hospitals of Europe The institutions at Berlin are reported as having the modern improvements and a talented staff

"Berlin affords some of the best examples of isolation hospitals in Northern Europe There the study of infectious disease is carried on with the patient assiduity and thoroughness characteristic of German modern science In the Koch Institute, established by the famous professor whose name it bears, all kinds of febrile disease are studied in a series of highly equipped laboratories by graduates and students, under the superintendence of highly qualified experts, presided over by the Professor himself In the adjoining grounds, close by the Charité Hospital, there is an experimental hospital laid out by Dr Koch upon his own principles, in which are treated all kinds of infectious disease, including tuberculosis and lupus Here it may be observed that all over the continent I found Dr Koch recognised as the leading medical modern exponent of the treatment of infectious disease and of bacteriologic science His pupils are already among the most prominent teachers in many continental medical schools, and some of their discoveries—notably that of Loffler in diphtheria—have produced highly beneficial results The principal hospitals in Berlin for the treatment of febrile diseases are the Moabit, capable of accommodating 900 patients, constructed upon the plan of single floored pavilions and for the most part of wood, the Friedrichshain Hospital, built in 1874, affording accommodation for general as well as fever patients and built in two, and in one or two cases, three floored pavilions, the Urban Hospital, opened in 1890, with accommodation for 600 patients of all classes, showing the most that can be made of limited space where ground is dear within a large city, and also built in two or three floored pavilions, and lastly, the Emperor and Empress Frederick Fever Hospital for Children, recently erected by the Berlin municipality, where the results of the most modern scientific research have been adopted in the general plan of the hospital, which is laid out in single floored pavilions "

PRACTICAL NOTES

For Infantile Eczema —*Dust* with the following powder Pulv zinc oxid gms 15, pulv amyli 32, pulv camphor 2 For itching, paint on the skin Tr camphor, tr benzoin co āā c c 32 —Dr C E Lockwood, in *Med News* September 26

New Treatment of Warts —Laubenburg has discovered that if a spot is touched with acidum nitr fum and then immediately afterward with acidum carbol pur liquef there is strong chemic action, the effects of which penetrate deep into the tissues and completely and permanently cure warts, condyloma, angioma, etc —*Cbl f Chir* , August 8

Permanganate of Iron in Eczema —The *Monitor Médico*, August 1, quotes from an exchange that both dry and serous eczema are successfully cured by moistening them two or three times a day with a 1 to 2 per cent solution of permanganate of iron applied on a cotton wad It is also recommended for other skin affections accompanied by pruritus

New Needle Lancet for Secondary Cataract —Stilling of Strasburg, has been using very successfully in his practice the last year and a half, a needle lancet shaped like the half of an arrow, its two cutting edges doing away with the necessity of using the cataract knife It is illustrated and described in detail in the *Revue Gen d'Ophthalmologie*, August 31

The Siesta and Digestion —Some *recent experiments are* reported in the *Gaz degli Osp e delle Clin* , of September 1, which demonstrate that a nap after eating weakens the muscular action of the stomach and increases the secretion of acid Repose in a horizontal position, without sleeping, increases the muscular action without increasing the secretion of acid The conclusions are therefore that it is advisable to lie down after a meal, but not to fall asleep, especially in case of dilatation of the stomach or hyperacidity

Multiple Vesical Puncture —Centra describes a case of retention of urine with serious symptoms due to asymmetric hypertrophied prostate He withdrew the urine by vesical puncture and in four days the congestion and hypertrophy of the prostate were reduced to such an extent that the patient could urinate normally The interesting feature of the case was the number of punctures necessary to effect a cure, three each day

They were made at different points along a horizontal line commencing 1 cm above the upper edge of the symphysis pubis, and produced no inconveniences —*Gaz degli Osp e delle Clin* , August 30

Gangrenous Hernias—Bogdanik suggests that better results will be obtained in gangrenous hernias if the pus and surrounding tissues are cleansed and disinfected before the peritoneum is touched He describes a case thus treated in the *Cbl f Chir* , August 15, proving the advantages of rendering the field of operation a clean wound before proceeding to the operation proper He adds that the scissors, knife and a few clamp forceps are all that is needed if the suture of the intestine is made exact

Celluloid Soles for Flat Foot—Kirsch recommends the use of celluloid instead of metal, for insoles in the prothesis of flat foot, as they require no skill in making and are exceptionally cheap, light and easy to walk on A sheet of celluloid 1 5 to 4 mm thick according to the weight of the patient, is placed on a cast of the foot and kept in place by a handkerchief, held by the twisted ends as a handle The whole is then dipped into boiling water for a minute or a half, which softens the celluloid The ends of the handkerchief are then twisted tighter, and the celluloid molded to the cast as it hardens It can be softened again as often as may be necessary The edges are smoothed level, cut into the proper shape and sand papered, and the under side made rough to prevent slipping in the shoe If the celluloid is painted with soluble glass it becomes almost fireproof, which is an important improvement for the celluloid bandages described in the JOURNAL, August 22, page 437, but is scarcely necessary for an insole —*Cbl f Chir* , August 29

Treatment of Sunstroke—Desanti's article in the *Gaz degli Osp e delle Clin* of August 30, commences with Do not let it happen In enlisting soldiers, for instance, it is much better to reject those who are liable to have sunstroke, men with weak hearts, anemia, or any chronic trouble, and alcoholics, in short, all those who have inherited or acquired a tendency to morbid conditions When sunstroke occurs, after removing the patient to the shade and loosening his upper clothing, the action of the heart must be stimulated and kept up with energetic friction and slapping, and the inhalation of a few whiffs of ether or acetic acid, water applied to the head, etc , and as he recovers, some stimulant given him to drink If the patient is exhausted from overwork, debility or malarial conditions, an intravenous injection of quinin should be made, or at least a hypodermic injection (4 grams each of hydrochlorate of quinin and antipyrin, in 6 grams of acq dist heated together If the solution crystallizes in the bottle it can be dissolved by slightly heating it again) He recommends that this solution should be kept on hand at times when it is liable to be needed Certainty as to malarial condition is only acquired by examining the blood, but as this would be impossible, and as quinin is comparatively innocuous, it is best to treat in this way all doubtful cases In severer cases with asphyxia, traumatic shock or intoxication from infection, it is of the utmost importance to excite the cardiac contractions, and the loss of a minute may cost a life Rotter advises an energetic revulsion on the cardiac region with a moxa, Mayor's hammer or blazing sealing wax, cauterizing or scarifying a large extent of surface and scattering salt upon it Direct excitation of the cardiac contractions with the electric current has been found effectual, but an electric appliance of sufficient power to send a current through the chest is not always at hand The best and most practical means to accomplish it is artificial respiration This can be Sylvester's method of raising the arms, or Pancini's raising the shoulders, or Laborde's rhythmic traction of the tongue, any way to introduce oxygen into the lungs and drive the blood into the heart There is no stimulant for the membranes of the heart that compares with the oxygen of the air, and Desanti has seen persons revive after they have given no indications of life for several hours As a supplement to the above treatment, he mentions the hypodermic injection of sulphuric ether, which has a powerful effect in stimulating cardiac action The surgeons of the German army are required to carry a Pravaz syringe on the march with a bottle of ether for this purpose, which practice, he adds, should be introduced into every army

NECROLOGY

SIR JOHN ERIC ERICHSEN, one of the foremost representatives of British surgery, died September 23 The distinguished surgeon was born in 1818, of noble Danish descent He was surgeon extraordinary to the Queen, ex president of the Royal College of Surgeons of England, and president of University College of London His contributions to scientific medical literature were extensive and important, especially the well known "Science and Art of Surgery" His "Concussion of the Spine" and the monograph "Railway Injuries of the Nervous System" showed his energy in another surgical division

N RUEDINGER, M D , of Munich, "the last of the old school of anatomists" His works on anatomy, descriptive, topographic and systematic, form an important part of the foundation of our present knowledge His folio atlases are in nearly every library, and the list of his contributions to science includes works on anthropology, embryology, histology of the organs of hearing, etc It is to him we owe the use of carbolic injections for cadavers He was one of the founders of the *Monatsschrift f Ohrenheilkunde*, and of a special magazine devoted to the anthropology and early history of Bavaria

G LAGNEAU, M D , Paris, noted for his profound anthropologic and hygienic studies which resulted in many practical measures of the highest benefit to his countrymen and to humanity He was member of the Academie de Medecine for twenty years

JULES ROCHARD, M D , Paris, aged 76, retired Inspector General of the Service de Santé de la Marine, President of the Académie de Medecine in 1894, of the French Association for the Advancement of the Sciences, and of various other scientific societies, a brilliant and classic writer and orator, "whose entire life was an honor and an example to the medical profession" His numerous works on hygiene, education, epidemics, etc , were rounded off by his vast work recently completed, the Encyclopedia of Hygiene Among his contributions to the *Revue des Deux Mondes* were articles on "Marine Hospitals," "The Rôle of Alcoholism in Modern Society," "Hygienic Education and Mental Overwork," etc He was one of the few who seem to have everything to complete their happiness, international honors, devoted friends and family, and perfect health until 1883, when he was shot by an insane person He apparently recovered from the wound, but the bullet remained in his breast, and recently produced the troubles which led to his death He commenced his career as a third class surgeon in the navy, and retained his love of the sea as a true Breton to the last His son Eugène is editor in chief of the *Union Medicale*

CHARLES MILNE, M D (University of the City of New York, Medical Department, 1873), at New York city, September 28, aged 56 He was a member of the Medico Legal Society of New York —Henry Hooper Mitchell, M D (Department of Medicine of the University of Pennsylvania, Philadelphia, 1812), at Elkton, Md , September 27, aged 76 years ——William C Caldwell, M D (University of Wooster, Medical Department Cleveland, Ohio, 1869), at Fremont, Ohio, of cancer of the stomach, September 29, aged 59 years He was a member of the Ohio State Medical Society and a contributor to various medical journals

MISCELLANY

City Physician of Bath, Maine —Eben J Marston, M D, has been appointed to this position, *vice* W H Tukey, M D, resigned

The Detroit Academy and Medical Association upon their first meeting, Monday, September 7, had pathologic specimens which were furnished by Drs H O Walker, Carstens and Longyear

To Drill Holes in Glass —The *Bulletin d'Apiculture*, No 119, states that holes can be easily drilled in glass with an ordinary trocar or drill, if the spot is first moistened with a drop of the following mixture Dissolve 25 parts oxalic acid in 12 parts of essence of turpentine, and add a chopped clove of garlic Set it aside for a week, stirring occasionally Pour it into a bottle and keep tightly corked

Training School for Insane Asylum Nurses —In response to demands of outside physicians a training school for nurses and attendants of the Cook County (Ill) asylum for the insane has been organized and a competent faculty, principally of medical men connected with the asylum, selected The course of studies includes physiology, hygiene, therapeutics, massage and allied subjects

The Pathological Society of Rochester, N Y, has petitioned the city council for an ordinance to allow the Mayor authority to grant permits for physicians to ride on the sidewalks with their wheel between 10 o'clock P M and 6 o'clock A M The Rochester *Herald* has a strong editorial recommending the council to pass the ordinance requested

Illness of Dr Hamilton —The editor of the Journal has been confined to his room, most of the time to his bed, with an attack of acute bronchitis since September 25 He was present at the Macewen dinner in compliment to that distinguished surgeon and the host, Professor Senn, but was ill then and scarcely able to speak, since that time he has not been out of his room His friends hope that he may be out in a few days He was relieved from the Marine Hospital last week

Retires From the Armenian Field —Dr Grace M Kimball, who is appointed assistant physician for Vassar, obtained a reputation for her bravery and work in Van in behalf of the Armenians Few laborers in that difficult field have remained so long and continuously without an interval of rest Worn out by the prolonged anxiety and the arduous duties of her medical and missionary work, Dr Kimball has decided to retire from the Armenian field, and after visiting the hospitals and schools in Europe, she will begin her college work in January

Cause of Electric Death —Experiments have been made by A M Bleile upon dogs in order to determine the cause of death in electric shock The conclusion reached is that for a given animal in a normal condition as to health a definite amount of electric energy will produce fatal results It is thought that the action of the electric discharge is to contract the arteries and increase the pressure of the blood, and that death is due to inability on the part of the heart to sustain the increased pressure of the blood so produced Postmortem examinations seem to show that the passage of the current does not cause any anatomic disintegration —*Popular Science*, September

Entertainment to Professor Macewen —Prof Nicholas Senn, president of the American Medical Association, gave a dinner at the Chicago Athletic Club, September 28, in honor of Prof William Macewen, of Glasgow, Scotland There were present Drs W T Belfield, John E Owens, Truman W Miller, Edmund Andrews, Christian Fenger, A H Ferguson, Captain Pilcher, U S A, Major Hartsuff, U S A, J H Etheridge, E J Doering, D A K Steele, Dr Cole, of Montana, E J Senn, G Wm Reynolds John B Hamilton, Jas A Lydston Speeches were made by most, if not all, of those present, eulogizing the honored guest, from which it can be inferred that the entertainment lasted into the "wee short hours ayant the twal," and was of a character well calculated to delight the genial Bobby Burns himself, had he been present at the affair The editor of this Journal regretted that illness compelled his early withdrawal

A Sleep producing Exercise Preferable to Hypnotics —Dr J B Learned, Florence, Mass, writes to the *Boston Medical and Surgical Journal* that he has experienced "infinite advantage" from moderate and varied muscular exercise as a means of inviting sleep On retiring put in use, by contraction, a certain group of muscles, change to another before exhaustion to another and thence to another, having a definite routine, and continue until a sense of fatigue has come The brain meantime is asked to keep a record of the respirations and of the muscular engagements in their order until it, too, says "Enough!" A few minutes generally suffices Will sufferers be willing to use any methods or agents foreign to the materia medica? Sleep immediately on retiring is restorative The drug does not make it so, continuously used Wine, tobacco, tea, coffee and late suppers, with social and emotional excitement often delay the hour of sleep My own personal needs were at the foundation of this "discourse" Conditions of the heart, digestion and nervous system should not be ignored in any case of insomnia The sufferers are abundant everywhere now

University College of Medicine, Richmond, Va —At a meeting of the faculty of this college Dr F S Harker, who has so efficiently filled the position of adjunct to the professor of histology, pathology, bacteriology and urinology, was unanimously elected to fill the chair made vacant by the recent death of Dr Charles H Chalkley Beside the special training which Dr Harker has received which fits him for the new chair, he has shown himself gifted as a teacher —*Va Med Semi Mo*, September

Phosphorus Necrosis —Mr Edwin Gould, who owns a large match factory at Passaic, N J, has recently promulgated an order that all employes who do not present, within a specified time, a dentist's certificate that their teeth are in a condition of perfect repair shall be discharged The danger of necrosis of the jaw from the phosphorus used in the manufacture of matches is well known, and he is said to have been induced to take this step by the fact that not long since an employe of one of the Diamond Match factories in Ohio, who had been attacked with necrosis, sued the corporation for $10,000 damages —*Boston Med and Surg Jour*, September 24

Anent Germs —Dr K N Bahadhurji of Bombay, in the *Indian Lancet*, July 1, 1896, concludes an exceedingly interesting critique upon "The Germ Fad," as so styled by himself, in the following presentation "Bacteriologic therapeutics is but a system of modern alchemy, and rests and proceeds on incorrect assumptions and daring guesses as conveniently abandoned as confidently set up Fortunately the germ scare is cooling down and germs will soon cease to be the objects of such anxious care and study, and will in time be consigned, in all probability, to the limbo of exploded myths which have had their day" The article is a long one and might advantageously be condensed for the pages of the Journal but what has been already quoted sufficiently displays its decided skepticism regarding the rôle of the bacillus, the wherefore of its being, the significance of its appearance, the explanation of its functions and the embarrassing schemes for its annihilation For the present, at least, we must conclude that there is no uncommon law in the governmental system of the microorganism, and may we not add no unique personalities, with extraordinary powers As has been said, we may multiply corroborations but add only a moiety to our real knowledge

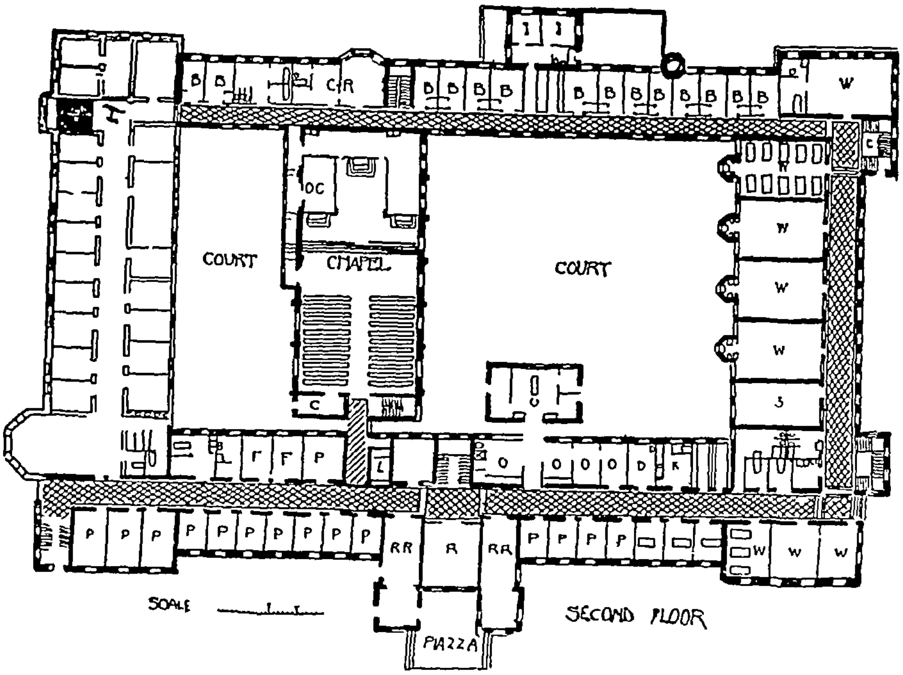
Calcified Fibroid from Cremated Corpse.—Dr. Yamagiwa of Tokio, in *Virchow's Archiv*, Vol. cxliv, part 1, 1896, describes a specimen of calcified fibroid found after cremation in the ashes of a woman in whom myoma of the uterus had been diagnosed during life. She died of paraplegia at the age of 70. When 28 she noticed for the first time a tumor in the hypogastrium, next year she married but never bore a child. The tumor grew slowly till she was 38, then it ceased to increase and became very hard. At 45 the patient lost her husband. When 50 she complained that the growth had become very heavy. In 1882 a doctor examined her, and noted that the tumor was of stony hardness and freely movable. Paralytic symptoms appeared and lasted for about three years, they reappeared seven months before death. Debility and emaciation then followed. Yamagiwa does not distinctly make out that the paraplegia was due to pressure of the tumor on nerves. The fibroid removed from the ashes looked like a petrified human brain. It weighed six pounds and ten ounces and measured from before backward nearly eight inches, transversely over five and one half inches, and vertically a little less than five and one half inches. On histologic examination uterine fibers were discovered. The mass was due to pure calcification and there was no ossification.

The Medicine Man of the Congo.—Among the Bakete, a tribe of the upper Congo river, the witch doctor rules supreme. The following is quoted from a recent lecture by a returned missionary. "The only attempt at religious rites is that practiced by the medicine man. In each town there are a certain number of medicine men, or witch doctors, but the medicine men of the town have no right to make medicine for their own town. Once in five years strong medicine is made. The doctors gather outside the town and hold a palaver as to the price to charge for making medicine, and after long haggling agree on a sum. They then enter the town and command that houses or open sheds be built for their accommodation and announce their intention of making medicine. The people are instructed that on the next day they must not leave their houses until noon, and the injunction is implicitly obeyed. Early in the morning the medicine men go into the woods and surrounding a tree that they know to be a medicine tree, speak to it thus 'O tree, we want medicine from you. We want good strong medicine. After having partaken of this medicine anyone who shall steal, commit murder, lie or do any wrong let him die.' The last word is repeated three times. The medicine men take the bark from the tree, grind it into powder and mixing with palm oil make it into balls the size of a chestnut. Returning to town they enter the huts prepared for them, summon the people and administer the medicine, repeating the words addressed to the tree regarding the penalty for wrong doing after having taken medicine. The natives thoroughly believe in the power of the medicine men."

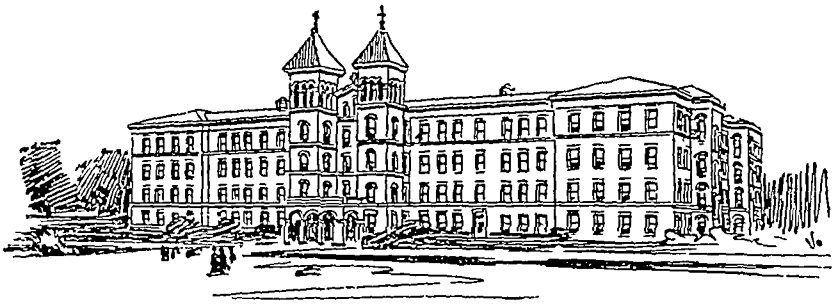
Regulation of Practice of Veterinary Medicine in Virginia.—A law has been passed in Virginia, taking effect May 1, 1896, which permits only two classes of persons to practice veterinary medicine or surgery in that State. 1, all persons who were, prior to that date, practicing veterinary medicine or surgery in that State, provided that before Nov. 1, 1896, they shall apply in writing to the State board of veterinary examiners and furnish satisfactory proof that they have been in practice in the State prior to May 1, 1896; 2, all persons who shall hereafter receive certificates from such board, and shall in all other respects comply with the law. Any person shall be regarded as practicing medicine or surgery within the meaning of this act who shall profess publicly to be a veterinary surgeon and offer for practice as such or who shall prescribe for sick domestic animals needing medical or surgical aid, and shall charge and receive therefor money or other compensation, directly or indirectly. But nothing in this act shall apply to residents of Virginia who confine their practice to the castration and spaying of live stock, nor shall it prevent any person from prescribing for live stock who does not claim to be a veterinarian or veterinary surgeon. The board of veterinary examiners mentioned is to consist of five members, learned in veterinary medicine and surgery, to be appointed by the governor, from a list of names recommended by the Virginia State Veterinary Medical Association. The board may prescribe rules, regulations and by laws for its own proceedings and government, and for the examination by its members of candidates for the practice of veterinary medicine and surgery. In case any applicant shall fail to pass a satisfactory examination he shall not be permitted to stand any further examination within the next six months thereafter or until the next meeting of the board, nor shall he have again to pay the prescribed $5 fee; provided, however, no applicant shall be rejected upon his examination on account of his adherence to any particular school of medicine or system of practice, nor on account of his views as to the method of treatment and cure of disease; and provided, further, that when, in the opinion of the president of the board, any applicant has been prevented by good cause from appearing before the board, the president of the board shall appoint a committee of three members who shall examine such applicant, and who may, if they see fit, grant him a certificate. Any person who shall practice veterinary medicine or surgery in violation of this act, shall be fined not less than $50 nor more than $500 for each offense, and it shall not be lawful for him to recover by action, suit, motion or warrant any compensation for services which may be claimed to have been rendered by him as such practitioner of veterinary medicine or surgery.

The Life Insurance Examiner's Decalogue.—The medical Department of the Prudential Insurance Company of America has issued the following ten commandments to their examiners. 1. Carefully read the medical examiner's instruction book. 2. Examine promptly in a quiet place, preferably at the home of the applicant, and allow no one to be present during your examination. 3. Answer each question and each subdivision of a question. Be explicit in your answers. Avoid indefinite expressions, such as childbirth, shock, grief, accident, injury, change of life, don't know, etc. Use ink in writing. 4. Pay especial attention to the average quantity of spirits, wines and malt liquors used daily. Give an average of each. If there is a history of previous excess give full particulars. 5. Give a full description of any illness in the history of an applicant, number of attacks, when last, duration and severity. 6. Describe the duties of the applicant. Explain trade terms used to denote an occupation. State the line of business or work. Note if occupation is hazardous or injurious to health, and see that the true occupation is stated. 7. Give careful attention to the moral hazard of the risk. 8. Be sure the urine you examine was voided by the applicant. 9. Be sure you examine the right person, and that you get the exact age, date of birth and a full family history. 10. Personally examine and personally secure and witness the signature of the applicant.

Substantial Professional Advance in Therapeutics.—The editor of the *American Therapist*, September, refuses to admit the gloomy views of those who look upon therapeutics as a thing of the past. While it may be true that too many practitioners rely on the empiric use of ready made pharmaceutics, and thus forget or never learn the rudiments of pharmacology and therapeutics, yet the proportion of scientifically and broadly educated physicians is increasing very rapidly in this country. The scientific study of therapeutics has never engaged more or better men than now. The proceedings of representative medical societies and current issues of legitimate and leading medical journals include a very satisfactory *proportion of contributions on therapeutic subjects.* These are the sources from which this journal draws much of the practical and instructive matter presented monthly to its readers—besides inspiring and printing many original contributions. One of our exchanges recently printed a pleasantly satiric letter from a correspondent who informed the editor that in this period of specialism, and finding most specialties "done to death," he had decided to adopt the *specialty of general practice*. That is the peg on which our contemporary should hang his "pessimism." Therapeutics is neglected by the average aspirant for publicity because it seemingly affords no special prominence; it is too general. Any 'ology, properly wooed, brings *reputation and distinction*. The broadly educated general practitioner, without a specialty, is too commonplace for average ambition. But the study of therapeutics is nevertheless indispensable—even in all specialties. Progress in therapeutics is constant, and we may hope with undoubting optimism that the fashion to study and write on drugs and drug action will spread through all ranks.



GROUND PLAN OF THE ALEXIAN BROTHERS HOSPITAL



THE NEW HOSPITAL BUILDING

The Alexian Brothers New Hospital in Chicago.—With imposing ceremonies the corner stone of the new hospital of the Alexian Brothers was laid Sunday, October 4. About 25,000 people were present to witness the laying of the stone by the most Reverend Archbishop Patrick Feehan. There was also a great parade by various Catholic societies, in which about 15,000 persons took part. The gay uniforms and ecclesiastic regalia gave an altogether old-world appearance to the pageant. The *Inter Ocean* says:

"Along the route the procession was greeted with much enthusiasm, most of the streets being lined with spectators. A number of houses were decorated with flags and bunting. When the first division reached the new building it marched on to St. Joshaphat's School, while the rest of the marchers broke ranks and joined the gathering crowds waiting for the laying of the stone. In anticipation of the ceremony a raised platform was built in front of the main entrance to the building. This platform was decorated with the national colors in flags and bunting. Over the platform was placed a canopy. In front of this waved the papal colors, surrounded by the national flag and those of a number of European nations. The platform was carpeted, and chairs were reserved for the invited guests behind the speakers' platform. At the west end of the platform was the stone, which was ready to take its permanent place in the structure after the ceremony. At 4 o'clock the platform was filled with guests and members of the Alexian Brotherhood, waiting for the arrival of the Archbishop and the procession. One of the earlier arrivals was Mayor Swift." We are indebted to the *Inter Ocean* for the accompanying illustrations.

Antitoxin Collective Investigation (Second) American Pediatric Society.—*To the Profession.*—The American Pediatric Society are encouraged to ask the co-operation of the profession in a further collective investigation. Laryngeal diphtheria is believed to furnish a crucial test for antitoxin; the present aim is to ascertain, 1, what percentage of cases of laryngeal diphtheria recover without operation, under antitoxin treatment; 2, what percentage of operated cases recover. The Society asks for records of cases of *diphtheria involving the larynx, whether operated or not, occurring in private practice in the United States and Canada, treated with antitoxin.* It is expected that cases occurring this year will be treated with reliable preparations of the serum, will be treated early, and will be given efficient doses The second report is designed to be a study of cases occurring between the closing of the first report, May 1, 1896, and the closing of the present collective investigation, April 1, 1897 In order to secure data which shall make the tables complete, circulars containing blanks for ten cases have been printed and are now ready for distribution It is desired that physicians shall fill out circulars (blanks) as cases occur, not trusting to memory, and shall urge their friends having similar cases to do the same Circulars can be had by applying to the committee (address below) Several groups of cases in the first investigation arrived too late and were lost to the report It is desired that circulars as soon as filled (ten cases) be returned to the committee The collection of cases must close at the end of March, 1897 For extra circulars (blanks), for returning circulars (filled), and for further information, address the chairman of the committee W P Northrup, M D , 57 East 79th Street, New York, N Y

THE ACTION OF THE SOCIETY UPON THE (FIRST) REPORT

1 Dosage For a child over 2 years old, the dosage of antitoxin should be in all laryngeal cases with stenosis, and in all other severe cases, 1,500 to 2,000 units for the first injection, to be repeated in from eighteen to twenty four hours if there is no improvement, a third dose after a similar interval if necessary For severe cases in children under 2 years, and for mild cases over that age, the initial dose should be 1,000 units, to be repeated as above if necessary, a second dose is not usually required The dosage should always be estimated in antitoxin units and not of the amount of serum 2 Quality of antitoxin The most concentrated strength of an absolutely reliable preparation 3 Time of administration Antitoxin should be administered as early as possible on a clinic diagnosis, not waiting for a bacteriologic culture However late the first observation is made, an injection should be given unless the progress of the case is favorable and satisfactory

Phosphorus Workers in Relation to Life Insurance —The *Medical Examiner* regards the manufacture of matches as an occupation that debars its workers from insurance examination

Around about Frutligan, in the Bernese Oberland district of Switzerland, a large proportion of the inhabitants are idiotic, due to the phosphorus used in matches In every house matches are manufactured, and in every house is a misshapen, grinning idiot This condition of things is due to an accumulation of hereditary influence, as the parents and grandparents for generations have been engaged in this industry The Swiss, as well as scientific and philanthropic people generally, deplore this state of things, and are endeavoring to devise means by which matches may be manufactured without sulphur or phosphorus Chemists are endeavoring to discover some substance for this purpose

The same thing occurs in France where matches are made In France matches are manufactured by the goverment The compensation is very small—something like one sou a hundred Matches are made of imported wood The government endeavored to substitute native wood, but the people objected, because with native wood they were not able to turn out as many matches, and consequently could not make as high wages, which amounted to about from two to two and a half francs a day They wanted to be paid by the day instead of by the piece As a compromise the old soft wood was allowed them on the condition that they should work by the piece

Another source of discontent was the danger attending the manufacturing of matches It is so detrimental to health that they wished government to grant those who do this work a pension, which was denied While yet young—say at 25—the operator will lose his teeth, they frequently become paralyzed and idiotic as before mentioned, and in nearly every instance there is experienced some form of ill health We remember while a student at Bellevue that the late Prof James R Wood used to hold up before his class a specimen of the lower jaw which he had taken from a patient who had introduced phosphorus into it by picking a decayed tooth with matches The consequence was a necrosed jaw The Professor used this instance not only to illustrate the danger of the above practice, but to show that bone would grow again if the periosteum was preserved In this case the jaw had been reproduced So far as insurance is concerned, those who make matches or work in phosphorus are not acceptable risks They should not be examined if their occupation is known to be of this character

Pan American Medical Congress —(*Telegram to the Journal*)—Cincinnati, Ohio, Oct 6, 1896 *To the Editor* —The official train for the Pan American Congress, Mexico City, leaves Chicago and Cincinnati November 10, A M , and St Louis, P M , same date, with sleeping and dining cars on special schedule for entire trip H L E JOHNSON, M D

Detroit

At the meeting of the Detroit Academy of Medicine, September 22, Dr David Inglis presented a report of "Three Postmortems "

The first case was a man 64 years of age, who had a history of previous injury Four days before the doctor saw him he had severe headache, but no vomiting There was some incoordination in using the legs and he found it difficult to climb stairs He yawned frequently These symptoms were progressive at the time he presented himself He had consulted a specialist who reported no affection of his ears, although there was a history of an attack of inflammation of the middle ear, ending in suppuration and accompanied by much tenderness over the mastoid cells

The doctor's diagnosis was impending apoplexy, but opposed to this was the fact, that there was no arcus senilis, arterial rigidity, or increased arterial tension The pulse was soft, 72 Motor symptoms were bilateral

Transverse myelitis was then suggested, in favor of which was the limitation of the motor defect to the lower extremities Systemic sepsis was excluded, there being no albumin found in the urine There was no evidence of poison from gout or malaria The old abscess of the middle ear was considered The motor defect in the legs increased, the headaches gave place to mental dullness and stupor, which ended in coma

The postmortem revealed no lesion of the brain substance The right half was compressed so that there was a space of half an inch between it and the skull which was filled with fluid The ventricles were empty, and there had been a large amount of subdural sero sanguineous effusion

Dr Inglis said "The postmortem is instructive in the following particulars First, it establishes clearly that congestion of the brain is a reality Authors, of late, have been inclined to ridicule the belief in congestion of the brain 'Gray,' in particular, discredits and resorts to the unscientific method of showing that no single one of the symptoms of cerebral congestions is pathognomonic, and that the prominent symptoms are frequently met with, individually, in various conditions "

The diagnosis of impending apoplexy was correct and based on the signs of severe cerebral congestion The case was first a serous effusion, not a hemorrhage, as first there was compression of the brain, and second, the blood formed a soft and thin layer everywhere over the cortex, and not a clot is found from a spreading hemorrhage, nor was it over both halves of the cerebrum

The doctor brought out the fact that a diffused lesion sometimes causes very limited local manifestations In this case although the entire cortex was involved sensation was perfect and the motor defect was confined to the lower extremity Had the case been minus stupor and headache the diagnosis would have been some lesion low down in the spinal cord In uremic poisoning the same principle applies, the poison pervading all parts of the brain, yet a part only may be selected for its paralyzing effect

Another point in the case is that the coma disappeared and the patient regained c [illegible] before de [illegible] h shows that unconsciousness does not always depend upon limited pressure, but upon increasing pressure, and with decreasing pressure consciousness may return while the pathologic conditions remain

The doctor called his next postmortem a riddle A boy aged 14, with a history of traumatism of head and back, developed choreic movements, which were bilateral He was dull, abstracted and answered questions slowly The choreic movements were such that it was impossible to listen to the heart sounds properly, heart's action was rapid and tumultuous, speech quite unintelligible

Six weeks after he was brought to Harper Hospital, where he was again examined He recognized Dr Inglis, but could not speak His left arm was powerless, but could use the fingers slightly, and raised the forearm like a flail The right arm trembled on voluntary motion Appetite ravenous Paralysis of left arm occurred some days before death Drs Emerson and Hitchcock thought the case was one of multiple sclerosis Dr Inglis a cerebellar tumor

A postmortem showed no nodules of any kind, but a large quantity of serum in the brain The liver was the seat of innumerable uniform, thickly disseminated nodules of some neoplasm The mesentery contained small nodules, but the glands of this organ were normal

This case was presented to illustrate the fact that it is sometimes as well to confess ignorance as to know many things that are not so The heart was normal and an operation over an arm center would have shown sound brain tissue

The third case was a man aged 25 While blowing water from a hose he felt a sharp pain in the back of his head This occurred in October, 1895 About the end of that year patient complained of pains over occiput, down the neck and across the shoulders No history of head injury The attending physician diagnosed rheumatism and treated him for a couple of weeks Then eye trouble manifested itself, and he was sent to Dr L E Maire, who diagnosed optic neuritis There gradually developed furious paroxysms of head pains, with vomiting, and sometimes bilateral convulsions and absolute loss of sight

When Dr Ingils first saw him, the pains were of such a nature that the patient would cry out Patellar reflex was entirely lost, ataxia marked, and when attempting to walk he tangled his feet and fell or leaned to his right Was slow in responding to questions, answering in a loud voice Was fretful and ate inordinately Diagnosis, cerebellar tumor, and in consultation an exploratory operation was advised He was trephined over the right lobe of the cerebellum, but no tumor could be found The postmortem in the temporal region revealed minute elevations of thin plates of bone covering points where it was almost perforated Twenty or thirty of these were found and were not confined merely to the region of the pacchionian bodies, though most numerous at the median line of the temporal bone The dura mater was found altered in structure and the pacchionian bodies enlarged The skull was found thinned at many places, especially at the parietal eminences, where, over an area as large as a silver dollar, on each side, the bone was as thin as card paper and could be easily broken with the fingers

Upon removing the brain a pint or more of sero sanguineous fluid escaped, which evidently came from the ventricles Upon incising into the brain substance, the trouble was found to be located in the cerebellum, both lobes degenerate, the left slightly more than the right It could only be called a degeneration, the substance being broken down into a semi fluid, resembling pus, though having no purulent odor The tentorium cerebelli was absorbed at the immediate site, and adjacent portions of the cerebrum seemed slightly affected There were found in parts of the ventricles, small adherent masses which appeared like granulation tissue

The diagnosis was confirmed to the extent that there was a cerebellar lesion, but not tumor of both halves

In closing his paper Dr Inglis said the postmortem was instructive in showing the remarkable thinness of the skull Had the patient received a blow upon the parietal eminence, it might easily have broken in the thin plate of bone Dr Inglis also said that the medico legal aspect of such a condition deserved notice

Dr J Flintermann read a paper entitled "Senile Dementia"

The Superintendents of the Poor for Wayne County (Detroit) have difficulty in finding room for the poor of the county in their new "county house," and for the insane at the asylum In the county house there are 807 inmates and in the county asylum 368 Dr E O Bennett, since being installed medical superintendent, May, 1881, has wrought many improvements The asylum farm of 160 acres is taken care of almost entirely by the insane

The buildings include the "county house," asylum hospital with chaplain's office attached, Wayne County Asylum, the new asylum erected in 1894, and double residence for the medical superintendent and book-keeper, the gas lighting and heating plant, electric light plant and outbuildings

For the last three years no acute febrile diseases have occurred in the asylum or county house, with exception of three cases of typhoid that developed in the latter

THE PUBLIC SERVICES

Army Changes *Official List of changes in the stations and duties of officers serving in the Medical Department, U S Army, from Sept 26 to Oct 2 1896*

Captain Norton Strong, Assistant Surgeon relieved from duty at Fort Sheridan, Illinois, and ordered to Chicago, Ill , for duty as attending surgeon and examiner of recruits in that city First Lieutenant John S Kulp Assistant Surgeon is relieved from duty at Fort Walla Walla Washington and ordered to Vancouver Barracks, Washington Captain William Stephenson Assistant Surgeon is relieved from duty at Vancouver Barracks Wash , and ordered to Fort Sheridan, Ill

First Lieutenant Powell C Fauntleroy, Assistant Surgeon is relieved from duty at Fort Grant Arizona and ordered to Fort Niobrara Nebraska, for duty Captain George McCreery, Assistant Surgeon, is relieved from duty at Fort Niobrara, Nebraska and ordered to Boston Mass , for duty as attending surgeon and examiner of recruits

Captain William B Davis Assistant Surgeon, granted leave of absence for twenty five days

Change of Address

Bennett Alice, from Norristown, Pa , to Wrentham, Mass

Grote, H W from New Orleans La , to Room 20, Oakland Music Hall, Chicago Ill

Harding George W from Twelve Mile to North Manchester Ind

Krousgrill D from Wadesville to 605 S 4th St Terre Haute Ind

Kilbride M Frank, from Spring Lake Beach, N J , to 2212 Green St , Philadelphia, Pa

Lebensohn, M H from 63d and Morgan Sts , to 692 Sangamon St Chicago, Ill

Motter Murray Galt from Head of 30th St N W , to 1017 14th St , N W , Washington D C

Russell, E S , from Tuscarawas, Ohio, to Room 421 Bissell Block, Pittsburg Pa

Sutton E M , from Masonic Temple to 328 329 Woolner Building, Peoria Ill

Von Koerber Paul E , from Loup City, Neb , to Casa de Correos City of Mexico, Mexico

Wright, John from Clinton Ill to 297 Reed St San Jose Cal

DIAGNOSIS IN DISEASES OF INFANTS AND CHILDREN

Read in the Section on Diseases of Children, at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga May 5-8 1896

BY C G SLAGLE, M D
MINNEAPOLIS, MINN

Candor compels me to admit that upon more extensive investigation than I have hitherto made, I found that much more had been done and said, and better done and said upon this subject than I was previously aware of, but found the subject matter widely scattered throughout voluminous medical literature

Inasmuch as we are compelled to study and practice every department of medicine before we can become at all skillful in pediatrics, it would be most unsatisfactory to attempt to discuss diagnosis in this special department without first reviewing the subject of diagnosis in general, as it applies more or less to all ages and conditions of life For we must and do endeavor to instruct our students, that pediatrics can never become "a specialty," as that term can only and properly be applied to the *study* and *treatment* of diseases of special organs or parts of the body, while pediatrics deals with the entire system, though only with "little men and women" And as the true "specialist' will be successful in his "specialty" just in proportion as he has mastered all departments of medicine, so the pediatrist will be proficient in his "limited practice" precisely to the extent that he has learned all other branches of our art

Some one has well said that the pediatrist must be a good all-round physician and something more, and we are here to-day to discuss that *something more* in our line, I shall only attempt to consider it more especially from the standpoint of the college instructor, and in its relation to our students and young practitioners The proper discussion of this subject would seem to suggest inquiries something like these 1 What is the import and scope of diagnosis? Wherein its intricacies, and what relation does it sustain to other branches of medicine? 2 What special features does it possess in its relations to diseases of early life? 3 What is the present status of this department of our art as compared with the past? 4 Can it be in any way rendered more accessible and comprehensible to our students and young practitioners? 5 Is there a demand for a treatise on the "Diagnosis of the Diseases of Infancy and Childhood, general and special, medical and surgical?

I can not presume to be able to answer all of them satisfactorily, except in a general way, but have endeavored to present in as concise form as seemed possible some suggestions along this line of thought for further elaboration in the discussion which it may elicit from you

If I may be pardoned for an attempt at definition of my subject, "Diagnosis,' before this learned body of medical men, it would be "the faculty of recognizing diseases so as to locate and name them with facility by the correct interpretation of their pathologic and clinical symptoms, and thus to be able to differentiate each one from all others"

Of the many difficult problems in medicine which confront our students on leaving our college halls to enter upon the general practice of medicine, diagnosis is the most difficult and puzzling So it probably was with most of us, and so it doubtless will be to them for years to come, despite our best efforts to assist and prepare them for it

We will not wonder that proficiency in the art of diagnosing is difficult to attain when we fully appreciate the fact that it is the practical application of all we really know of medicine It is the apex of the grand pyramid of medical science and art, whose base has been founded upon the enduring principles of anatomy, physiology and pathology It is, therefore, the real practical test of every physician's medical education and skill, and just in proportion as he possesses faculties and facilities for correct observation and analytic reasoning will he become proficient in correctly interpreting the various phases and symptoms of disease, and we all appreciate the fact that it demands even more skill and native tact to rightly interpret the various peculiar phases of morbid action in infants and young children, where we are deprived of the aid of speech, and who are often unapproachable, than it does in adults where we can better secure from themselves the history of the case, the location of the pain and the important subjective symptoms which they are experiencing

Diagnosis to the skilled physician is much like an intricate case at law being tried before a competent judge, who renders his decision only after all the conflicting evidence "is in' and carefully weighed and sifted And as anatomy, physiology and pathology are the "A B C" of medicine, so etiology and symptomatology (illuminated by ample clinical and laboratory investigations) are the "cathode rays' which illuminate the deeper hidden mysteries of disease and render them accessible to our comprehension

Dr Dorning has well said that "The only enduring foundation for the superstructure of diagnostic proficiency is in systematic and exhaustive study at the bedside combined with *diligent and conscientious* research in the laboratory'

It is a lamentable fact that many men in our profession never make good diagnosticians even after enjoying ample opportunities And it has been demonstrated to me many times during my long professional life that many otherwise fairly good practitioners have betrayed th [illegible] defective in diagnostic [illegible] faculty

There seems to be with some men something like "a natural tact" in this matter, which only a comparatively few possess in any eminent degree But if all can not be Da Costas in this faculty, we probably have a right to expect that our students can and ought to be taught to recognize at least typical forms of disease as they meet them on entering general practice

The faculty of correct and systematic examination of the patient seems difficult for many men to learn They seem to proceed in a rambling and desultory manner, as if they had no specific aim, to accomplish either by questions asked or in their estimation of the value of essential symptoms And this, too, notwithstanding our best endeavors to teach them system, and emphasizing the fact that they are often required to ascertain what the disease is *not*, in order to determine what it *is* "Diagnosis by *exclusion*, *negation* or *elimination*" so exceptionally well illustrated by Da Costa

After a thorough familiarity with all the departments of medicine, and an ability for systematic examination of the patient, our diagnosis will be predicated for the most part 1, upon the "physical signs" as they appeal to our trained special senses, 2, the symptoms as they indicate deviation of function, 3 the history of the case as we elicit it from the patient or friends

Diagnosis being a science and art, which teaches us to distinguish one disease from another by tracing symptoms to the causes from which they originate, must be valuable not only for purposes of *treatment*, but enables us also to form a correct opinion as to the *result* of the disease (*i e*, prognosis), for without correct *diagnosis* there can be no correct *prognosis* nor treatment

We have all seen physicians, with more ingenuity than skill, excuse their inability to render an exact diagnosis by assuring the interested parties that an exact diagnosis is no longer demanded in most cases, as we do not now treat the *name* of a disease, but have learned to search out the *indications* of treatment and meet them *pro re nata* with our therapeutic agents All of which might sound satisfactory to the unskilled, but would hardly satisfy a diagnostician, for he will understand that, as a rule with few exceptions, we can only learn the "indications of treatment" by recognizing the disease, that we must know what the disease is, its true nature and location before we can expect to remedy it

Doubtless many young physicians fail at first in diagnosis from the fact that they have not yet sufficiently acquainted themselves with normal conditions and processes of the human system, notwithstanding we are emphasizing the facts before our students as much as seems possible that they *must* become well acquainted with *normal* appearances before they can appreciate the *departures* or deviations, that they must know what symptoms mean in individual cases before they can combat them successfully, and often in order to illustrate and emphasize our teaching, remind them of the impossibility of treating successfully such symtomatic conditions as we meet in eclampsia, dropsy, jaundice, dyspepsia, constipation, headache or even *pain*, fever and many like morbid phenomena, which we all know are only external exponents of various internal processes, without *knowing* the *nature* of the proximate *cause*

All that has thus far been said and all that can be said of the intricacies and learning and skill requisite to meet the complexities of diagnosis in general, obtains in accentuated form in the diagnosis of the diseases of infant and children, for we soon recognize the fact that exact and even early diagnosis in the various ailments of young children is more important often than it would be in adults, partly, it may be, on account of the demand for early prophylactic measures being enforced, if it should prove to be an infectious disease to which young children are peculiarly liable as also from the well-known fact that many acute ailments run a more rapid and violent course in early life So intricate, indeed, is this matter that few of us, perhaps, will ever become so gray, experienced and skillful that we may not sometimes make mistakes in diagnosis I yet remember when Professor Yandell of the University of Louisville, Kentucky, apologized to the class for his inability to render a diagnosis in a case which proved upon postmortem to have been gangrene of lungs, by assuring us that he had followed the great Louis through the wards of the hospitals of Paris and saw him write over some of the beds for several days together, "No diagnosis "

Many ailments of young children simulate each other in clinic features so closely that it is impossible for a while to render a positive differential diagnosis Not long since I saw an attack of what proved to be typhoid fever in a child diagnosed for several days as "meningitis," without much suspicion of its incorrectness, on account of the peculiar cerebral and neurotic symptoms present, and this, too, by several of our most skillful and experienced physicians

Who of us have not, at some time, been perplexed for a while in rendering a differential diagnosis between such similar appearing affections as "non-specific pseudo-membranous laryngitis" and true "diphtheritic laryngitis," or between convulsions (centric or eccentric) and epilepsy, or between pertussis in its first stages and catarrhal bronchitis in young children?

Professor Jacobi has truly said 'that there is scarcely a tissue or organ which behaves exactly alike in the different periods of life," and the same distinguished author reminds us (Cyclopedia of Diseases of Children) that pneumonia, tuberculosis, typhoid fever, rheumatism, epilepsy, diabetes and many other affections of the young differ considerably from the same affections in the adult in their clinic symptoms, and even sometimes in their anatomic aspect But of all the manifold ailments of early life perhaps none are more generally difficult to diagnose correctly and promptly than the various protean, nervous and cutaneous affections, to determine whether they are simple or complex, idiopathic, symptomatic or sympathetic whether organic or merely local or functional in their nature

One of the most unsatisfactory features of diagnosis in young children has often been the impossibility of eliciting or of correctly interpreting the "physical signs" in affections of the heart, lungs, pleura, etc, this partly from the deviations of the sound elicited upon percussion and auscultation, and partly it is often from our inability to approach or control the child in a satisfactory manner I doubt, indeed, whether physical sounds in the chest afford us the assistance in diagnosis in young children that they do in adults We are constantly reminded also that not only do diseases more frequently hybridize in early life, but also that many of the causes, symptoms and even diseases themselves are peculiar to that period of existence

It is a recognized fact that diagnosis can sometimes be either confirmed or corrected by noting the peculiar behavior of our therapeutic agents in special cases, notably, opiates, antipyretics, digitalis, belladonna, etc , more especially liable to be manifested in cerebral, cardiac and certain pulmonary affections, typhoid fever and other diseases in the young All of these peculiarities and perplexities in the diagnosis of children's affections are being emphasized and elucidated in many ways by those who are authority in these matters, and the advances in pediatrics and helps in methods of diagnosis within a few decades have been most gratifying, especially to some of us older members of the profession When I entered the medical profession in 1859, pediatrics was in its infancy in this country I know of but one text-book at that time exclusively upon "Diseases of Children," by an American author, and that was by D F Condie of Philadelphia, and almost without tables and illustrations, which constitute such an admirable feature of all our recent text-books on pediatrics, which are now numbered by the dozens

At that time pediatrics had little recognition in any of our schools I remember, however, that a great impetus in the evolution of this department was inaugurated very soon thereafter (about 1860) principally through the efforts of Professor Jacobi of New York, who, as you all know, has by his talent, energy, zeal and enterprise contributed as much as any other man in America toward the advancement and present elevation of pediatrics in this country He it was, who, nearly forty years ago, took the initiative in placing this important department of medicine upon the high plane which it justly merited in medical science While his laudable endeavors have been nobly seconded and supplemented by a host of younger co-workers of equal talent, energy and zeal, and hence the names of Jacobi, Condie, Smith, Meigs, Keating, Pepper, Holt, Starr, Rotch, Chapin, Northrup, O'Dwyer, Koplik, Osler, Gibney, Love, Edwards and a host of others too numerous to mention here, but of equal ability, have become known and honored throughout the world of medicine, more especially by their efficient labors in this department And it is pleasing to know that among these distinguished names are the authors of our most popular text-books on pediatrics Truly, "by their fruits we shall know them" America has done well, may their good work go on

It is very satisfactory to find that they have done about all that seems possible to be accomplished in text-books to facilitate diagnosis for instructors, students and young practitioners by so thoroughly illustrating the phases of disease in early life by introducing numerous colored plates, photographs, tables of contrasted symptoms in similar diseases, temperature and other charts, analytic tables of blood, foods, urine, etc , together with details of clinic cases, etc , all of which prove very helpful to both teacher and student, and are in pleasing contrast to our text-books of only a few years ago

As to the exact assistance which the new science of bacteriology and the late advance in photography are yet destined to aid us in this field, can hardly be fully estimated, but the possibilities seem very great, and what they have already accomplished seems wonderful, for from the well recognized intimate connection existing between pathology, etiology symptomatology and diagnosis, whatever contributes essentially to the better understanding of the causes, nature and symptoms of disease must afford greater facilities in rendering exact diagnosis, and it is thus the fever thermometer, camera and microscope have served as our most valuable agents as "instruments of precision" in this matter Nor can we ignore what applied chemistry has achieved along this line in the investigation of foods, the blood of infants, ptomains, leucomains, urinary analysis, etc , all of which are fully demonstrated in our late text-books

Since I began the preparation of this paper at least two new works on general diagnosis have been announced as "in press" One on "Clinic Diagnosis, by Charles E Simon of Johns Hopkins Hospital, being "Diagnosis by Microscopic and Clinic Methods," says the author, and the other, "Herrick s Handbook of Diagnosis, ' by James B Herrick of Rush Medical College As to how far they will meet the demands in this especial department will soon be apparent Prof J L Smith s publishers have also announced a new and carefully revised edition of his popular text-book on "Diseases of Children rewritten and profusely illustrated, which will be cordially received by students and faculty Professor Rotch has also announced a revised edition of his admirable lectures on pediatrics His style of treating the subject and method of illustration of the text to facilitate diagnosis could hardly be surpassed Nor must we fail to accord to the "American Text book on Pediatrics" its full share of merited commendation for its painstaking thoroughness to meet the requirements of our students

While the 'Cyclopedia of Diseases of Children' marks a new era to pediatrics as a monument of talent and enterprise not even confined to this continent, but cosmopolitan in its research and I shall venture to assert as bearing directly upon this subject, that the chapter there on the general diagnosis of diseases of children by Professor Finlayson of Glasgow could hardly be excelled in its comprehensive and systematic details of the great general principles of diagnosis in diseases of children I have never seen anything on the subject so comprehensive and practical

But after all the good work that has been done and is being done to facilitate diagnosis for our young men just entering the medical profession, it remains a lamentable fact that a great many of them are very deficient in the faculty of diagnosis when put to the test on examinations for graduation, and on going before the State medical boards of examiners for certificates to practice medicine At least I am sure this is true of our classes in Minnesota and through the West and Northwest This results from several causes, which we are endeavoring to remedy as fast as practicable, as, 1, insufficient literary education on entering our medical schools 2, too short course of instruction in most of our schools 3, lack of ample facilities for clinic observation in our smaller cities, 4 text-book instruction in this particular line too voluminous for the generally limited time and means of our students

This, then, can only be remedied by 1 higher literary requirements in some of our schools upon entrance examinations 2, longer and more terms of study and instruction in the same (at least four or five years of eight or nine months each) 3 is far as possible a more earnest endeavor on the part of our faculties to afford the students [illegible] ample facilities for clinic study and observation in hospitals, dispensaries, laboratories, etc., 4, possibly, by some good, concise text-books illustrated by copious plates, tables, etc., on the diagnosis of diseases of infants and children, where much of the best literature on the subject might be carefully revised and compiled and presented in the best possible form for the study and limited time and means of our students, only to supplement the good work which has already been done by our popular authors of text-books on pediatrics.

We, in the Northwest, are realizing more fully every year the necessity of raising our literary requirements on entrance to our medical colleges, and are doing so as fast as is practicable, both medical schools in Minneapolis having now raised their entrance requirements to a certificate of graduation from one of our best high schools, or its equivalent of other high-grade schools, and have also lengthened their curriculum from three years of six months to four years of eight months each, and hope to be able soon to go beyond this, thus emulating as fast as possible in the West the best medical schools in the East. Applauding as we do most heartily the great advances being made in such high-grade schools as Harvard, McGill and some others in the Northeast.

The advance has been gradual but continuous, from two years of four months each, and almost no recognition of pediatrics, as in the University of Louisville and many others when I began the study of medicine in 1859, to four years of eight or nine months each, as in most schools at present, and a thorough recognition of the importance of diseases of children in all, is truly gratifying, and the preliminary requirements for entrance to most of our medical schools have been advanced in like manner.

I believe much of the late advance has been stimulated by the rigid exactions of legislation in creating and regulating our State boards of medical examiners for license to practice medicine, especially in our great Northwest.

What then is the conclusion of the whole matter? I think it can readily be summarized about as follows:

The principal factors in acquiring both general and special diagnostic proficiency are 1, time, 2, opportunity, 3, application, and inasmuch as authors and schools are coöperating to encourage as fast as possible longer terms of study, more ample opportunities, and, in every available manner, stimulating the students to more diligent application, and with ever increasing help in all directions, there does not seem to be much fallow ground to cultivate in this field. It would indeed appear that about all is being done to elevate medicine and facilitate diagnosis that can be suggested, and in conclusion will only say, that while I have thus in a desultory way endeavored to emphasize some of the features which my subject suggests, I entertain a painful apprehension that my effort has been disappointing to some of you on account of the *importance* of my theme. But if it only succeeds in provoking a discussion, here, along the lines indicated, I shall have accomplished to some extent, at least, my purpose in presenting it to you, insisting, as I beg to do, that its design has been more *retrospective* and *reminiscent* than otherwise, for it would be difficult indeed to say much new or original on a subject which has been so well developed by the greater minds of the medical profession.

In what proportion of cases in young children, i. e., under 2 years, does the average physician render a correct diagnosis on first examination? Answer. Only about one-half, and in older children possibly three-quarters while an expert may correctly diagnose four-fifths even in young children, i. e., infants, on first examination and in older children nine-tenths.

DISCUSSION

Dr. J. A. Larrabee, Louisville, Ky.—The vital point in pediatrics turns on the diagnosis. In fact, it might be said this is to the general practitioner an opprobrium medicatoris. We all know it is in this department the greatest perplexity arises and the greatest skill and judgment is required, and even then we frequently fail to make a correct diagnosis. Too much education can not be given. And while I have all esteem for one who is accredited a peculiar genius of making instantaneous diagnoses, I believe such men very often make very grievous failures. While we differ from each other in that capacity as in others, I believe it was Michael Angelo who said, genius is only another name for hard work. I do not believe we will arrive at immediate diagnoses unless we do hard work. It is along this line great stress may be laid on educating medical men. The essayist has spoken of diagnosis, but in my mind has omitted a very important part, that is the aids to diagnosis in diatheses. It seems to me the diagnosis is greatly enhanced by the study of diathesis. There is in every one of us a weak spot by inheritance. That which would affect one would not affect another. Hence, in diagnosis we should avail ourselves of all the knowledge we can obtain. We do know, families travel on family lines and disease is more prone to come along these lines. And by seeking along these lines we will be more likely to arrive at the diagnosis than by rambling. I invariably insist, upon the first visit, no matter what the disease may be, on the complete, careful, thorough examination of the nude body. In his advice to his students, Hippocrates said: "View the body outstretched," and that applied to adults as well as children. If we attempt a diagnosis without this, when we have not seen the patient before, we will fall into very palpable errors. How many gentlemen here have had their attention called to a rachitic condition or a case of catarrhal pneumonia, in which the child is dying not so much from the pneumonia as from the general condition? A single pustule may point the way to the disease better than anything else. Thus we are to watch closely, for every little point is a big point. The strain is such we must call in all our senses, and even then we have not quite senses enough. In closing I wish to refer to physiognomy in disease. We must study the countenance of the child and interrogate that.

Dr. Samuel E. Woody, Louisville, Ky.—The diagnosis in children does offer a great many difficulties not encountered in the adult. The absence of the power of speech at that tender age, the excitability of the nervous system, the perversion of the spoiled child, the fear and agitation of the nervous child, offer difficulties to be overcome only by the greatest amount of tact and patience, just the qualities in which the doctors, perhaps, are oftenest failing. And then, again, diseases run a very exaggerated course. The progress of the disease is so rapid, unless we are careful and visit the patient early, we are not apt to detect the symptoms. The history is rapid. As to the physical diagnosis being more difficult in the child than in the adult, I have not found it so. Pain sets its mark most of all upon the child. Look at the face and you can tell the sick child at a glance. I believe inspection gives you more assistance in children than in grown people. The examination of the chest offers greater assistance in the child than in the adult, especially when the child is asleep. Not only can we hear through the chest walls better, but the walls are thinner and we can palpate better. And here lately, since the employment of the Roentgen photography, we find the thinness and translucency of the tissues of the child is very important. Only lately a photograph of a child has been published, in which the outline gave also an idea of the density of the tissues In my clinic we got good results in the examination of rickets The bones made scarcely a shadow, giving ocular demonstration of the diagnosis already made of rickets I don't think, Mr President, there is any field in the practice of medicine in which the diagnosis can be, if the proper amount of patience is used so easy, so thorough and so satisfactory

---

SEPSIS OF THE NEWBORN

Read in the Section on Diseases of Children at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Georgia, May 5 8 1896

BY HENRY E TULEY, A B , M D

Member of the Kentucky State Medical Society Clinical Assistant to the Chair of Practice and Instructor in Physical Diagnosis in the Kentucky School of Medicine, Louisville Visiting Physician to the Masonic Widows and Orphans Home Associate Editor and Manager Mathews Medical Quarterly, etc

LOUISVILLE KY

The history of the following case is reported as the text for a few remarks upon sepsis in the newborn, not only because of its rarity, but because of the interest attached to the case in connection with its etiology

Baby T was born on February 1, 1896, of a healthy primiparous mother after a normal though rather tedious labor which had to be terminated by forceps The child was a male weighing about seven pounds, cried well and was quite vigorous

The mother had no vaginal discharge before labor, but a vaginal douche of 1-2,000 bichlorid of mercury was given her upon the advent of the first pain, none were given afterward Her puerperium was perfectly normal and afebrile

As soon as the head was born the eyes were wiped and the face was washed, the first bath being given some hours later The cord was tied with a piece of silk from a skein which had been used the day before in an ovariotomy and some of the same was used the next day in an abdominal operation without further preparation After the first bath the cord was dressed with talcum powder and wrapped in absorbent cotton

During the first three days nothing abnormal was noted with the child, it had a normal temperature, nursed well though apparently not satisfied, slept well and had normal movements On the fourth day a temperature was reported of 101 4 degrees in the morning at 6 o'clock and it had risen to 104 degrees by noon I was asked to see the case at this time by the attending physician, Dr L S McMurtry, by whose courtesy I report it now It was decided that the temperature was a starvation one and that artificial feeding was indicated, it was accordingly put upon cow's milk, well diluted, to supplement each nursing, temporarily, as the breasts were at this time beginning to secrete This reduced the temperature in five hours to 100 6 degrees, and the next day the temperature was normal and the child seemed as well as usual The cord dropped the next day, the fifth, leaving a moist base, which was treated aseptically and dressed with talcum powder The next day the temperature rose to 102 4 degrees and the child was reported as listless and slow about nursing I was asked to see the child again, at this time and on close examination found a retracted umbilicus which, on depressing the edges, was found to contain about twenty drops of pus, this when wiped away showed the base or stump of the cord to be fungous in character The child did not stand manipulation of the parts well, pain being caused when they were cleansed, and there was noted slight distention of the abdomen After thorough cleansing of the navel with a bichlorid of mercury solution, the fungous navel was touched with a twenty grain to the ounce solution of nitrate of silver and a powdered boracic acid dressing applied This dressing was renewed twice daily and the silver solution used as before

The progress of the patient from this time to its death, three days later, is of no particular interest save that the temperature rose continuously and steadily from an initial one of 102 4 to 107 degrees a few hours before its death Baths would reduce this a degree or so, but it would rise again in a few hours It refused to nurse and was with difficulty fed breast milk, which had been pressed out for feeding with a medicine dropper The day before its death it had passed very little urine and had several movements, which were composed almost entirely of mucus The bowels were irrigated with plain water which regulated this condition to a degree and also increased the amount of urine voided On the day it died the skin was very hot and dry and it was put in a hot air bath, but this caused so much prostration that it was removed and stimulation kept up to the time of its death A few hours before this occurred its hands and feet were noticed to become a purplish color, perfectly cold and this condition had extended to the wrists and nearly to the knees before death The abdomen was much distended and tender, the navel moist and the granulation tissue covered with pus, though none could be forced from the vessels by pressure upon the abdominal wall

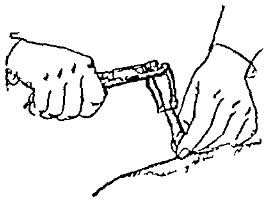
This case is of particular interest because of the following facts The child was born of a healthy mother who had been in the hospital under the daily observation of the physician and nurses for nearly one month before her confinement, the labor occurred under the most carefully prepared aseptic surroundings, in a hospital where a great deal of abdominal surgery is done and no deaths had occurred in more than a year, and that one in another part of the building, it was the first case of obstetrics which had ever been at the hospital, the mother had a perfectly normal and uneventful convalescene and had no vaginal discharge before labor the patient had an experienced trained nurse, on special duty, in charge and more than the usual care was taken with the dressing of the cord, careful bathing and talcum powder being used The question has arisen "Where did the infection come from which caused this child s death?" That it occurred through the navel there can be no doubt

The literature of sepsis of the newborn is very meagre but a number of cases have been reported The following routes for infection have been mentioned The umbilical cord and its stump are the most frequent points of infection among others mentioned by Brothers are the following Accidental injuries or operations with unclean instruments mammary abscess tongue tie or circumcision abrasions of the buccal mucous membrane, or slight injuries to the genitals or anus septicemia of the mother during intra-uterine life premature rupture of the membranes putrefaction of the liquor amnii and aspiration of this by the child causing a septic pneumonia a violent vaginitis of the mother acquired during the last weeks of [illegible] premat[illegible] rupture of the membran[illegible] ns tra mitted from the mother, by means of her milk, when she has septicemia following labor

Jacobi mentions the gastro-intestinal tract as a frequent site for infection, but in his writings, decidedly more prominence is given the umbilicus and its care as a means of prevention of sepsis The pus of an ophthalmo-blennorrhea or the decomposing lochial discharge, he also mentions as causes

In the case reported all of these sources of infection can be eliminated save the umbilicus There were no operations done upon the child, the buccal mucous membrane was normal, the mother at no time had symptoms of sepsis, a vaginitis, or decomposing lochial discharge, and frequent examination of the lungs of the child failed to reveal any lesion

The time of infection in the case can not be decided, but that it did not occur at the time of tying the cord *and its first dressing is certain* There was no septic condition existing in the cord before it separated, as it mummified rapidly and was perfectly dry throughout after the separation It most likely occurred after it became detached, through the fungous navel left, though extra precautions were taken in its care A possible cause, perhaps, was by septic matter being carried through a wet napkin by capillarity, from the alvine evacuations It is a common complaint of nurses that boy babies are with much more difficulty kept dry, on account of the napkins being wet high up, thus soiling the bands and cord dressings



It does seem queer, however, that sepsis should have existed in this case, in which every attention was paid to the details of asepsis and antisepsis in the lying-in-room, especially so when we think how common it is for no dressing to be applied to the cords of children of the poorer classes, or if one is applied it consists of a greased cloth, after which gangrene is the more apt to occur, or simply a rag with a hole burned in it, with ashes or soot as the drying powder

However, the occurrence of sepsis in one case, where every care has been taken to prevent it, should not encourage us to relax our vigilence in preventive treatment The treatment is still mainly preventive, and in the majority of cases, sepsis can be prevented In a series of 222 cases at the Sloane Maternity Hospital, New York, personally seen by the writer, no case of sepsis in the newborn occurred and no trouble with the navel The possibility of its occurrence, however, should always be kept before us, careful sterilization of ligatures and instruments used in severing the cord should be had, as well as of the hands before this is done The ideal ligature is the rubber one, and the difficulty has always been in obtaining a method of applying, but in the ingenious instrument devised by Dr A C Kellogg, which I take pleasure in exhibiting, with which a small rubber ring is applied to the cord, all danger of sepsis from the primary ligature is obviated because of its ready sterilization, and hemorrhage simply can not occur

The after-care of the cord is important, there should be a separate bed for mother and child, careful cleansing of the hands before bathing the child, which should always be done before the mother is attended to, the avoidance of fatty applications to the cord and the use of drying powders to facilitate the mummification, a very good formula being salicylic acid and pulverized starch, one part to eight

The care of the cord is of less importance than the care of the stump, every detail in the treatment of any surgical wound should be observed here Should there develop an omphalitis, gangrene of the umbilicus, an arteritis or phlebitis, the most active stimulation is indicated with prompt attention to the proper cleansing and antiseptic treatment of the stump, the only precaution being the avoidance of carbolic acid as an application The symptoms of them all are more or less similar, local appearance of the inflammation at the umbilicus, it being generally bathed in pus, peritonitis is always present to a greater or less degree, also pain and tenderness especially during the bath, and a septic temperature

However, there may be no symptoms, the condition being recognized only at the autopsy table

111 West Kentucky Street

DISCUSSION

Dr J A Work, Elkhart, Ind —What substance do you use on the cord as dressing? Answer Cotton

Dr W B Parks, Atlanta—I would like to ask the Doctor if it would not be well, in the large cords, to make a little massage and lessen the size of the cord before severing it That can be done without any injury, I think, if you dress the cord near the child and manipulate outward By a little compression in this way, you can lessen the edematous condition I have done that myself quite successfully in a few cases I never like to tie these large cords for fear of there being too much to be absorbed

Dr A C Cotton, Chairman—The advantage claimed for the rubber is its constant elasticity gradually displacing the Wharton's jelly

Dr Hatch—I have never lost a child under those conditions in my entire practice It has been my practice during the last ten years, not to sever the cord until the placenta is born, and since I have adopted this method have had better success with the children and they get along better I do that uniformly and so far as having sepsis is concerned I have for a great number of years used thoroughly sterilized silk in tying the cord I can see the advantage of this band Last spring I tied one of those large cords and thought I had tied it thoroughly, and imagine my surprise when a few hours afterward I was sent for and it was said the baby was bleeding to death I can readily see the constant pressure of the elastic band would have adapted itself to the cord as the edema diminished The hemorrhage in this case was due to the edema leaving the cord, allowing the ligature to slip off

Dr Gray—I have been in the habit of doubling a small rubber band three or four times and slipping it over the cord I have done that several times when there was considerable jelly of Wharton, with good results

Dr J H Ross—In the country where I practice, I think it is the custom to use almost any substance at hand for ligature I prescribe flax or cotton thread But I invariably ligate the cord before I cut it off, and it occurs to me now that perhaps the chances of infection would be lessened by the ligation being made before the cutting is done We have not been using, in country districts, antisepsis about the cord and I do not remember a single adverse occurrence in the history of many hundreds of cases

Dr A C Cotton, Chicago—Well, we have tied the cord with almost everything I have tied it with shoestring and with a hair string from the head of the woman a good many years ago, and no ill results ever followed it The only case I have ever had of infection from the navel was long after I had been connected with a hospital and had been taught surgical asepsis and practiced it In my experience and observation sepsis from the navel is a rare thing in our city, and midwives take no aseptic precaution at all in many instances That it should follow in the practice of men who observe aseptic precautions religiously and not occur in the practice of people who do not know the meaning of the word "asepsis" is a mystery to me The discharges ascending the napkin by capillary attraction, is an argument that has been used by myself, as those will remember who heard me at Baltimore and the Illinois State Medical Society last year I have substituted an absorptive pad making the diaper simply a key bandage to hold the pad in place, the pad being made of such material as to absorb readily, so the outer retention band is not wet at all

Dr **Henry Tuley**, Louisville, Ky —In the case I have just related the enlarged cord extended fully five inches directly from the navel of the child and it would have been impossible to strip this so as to get a good place to tie the ligature That case was used as an argument for the rubber ring In the series of 272 cases there were some twenty or thirty cords which bled secondarily, after the tying of the ligature In some very fat cords hemorrhage would occur I think this case stands as a unique one and one which I can not fully explain as to the cause of infection Every precaution possible was taken with the case, because it was a patient recommended to Dr McMurtry by a friend in Glasgow, and under that recommendation it was with the greatest care the case was watched Without any further preparation the Doctor used the ligatures the next day in an abdominal operation But still that possible cause of infection should not be forgotten I think it does sometimes occur in that way I was approached last year by a prominent professor in one of our colleges in Louisville and he said "What are you going to say about the umbilical cord?" I detailed to him the case I suggested He said "That is all a mistake Just recommend it be left alone entirely, just turn it loose and it will take care of itself" To my personal knowledge this professor has had several deaths in the newborn, and I think if he would examine them carefully, get an autopsy, he would find the cause to be sepsis We know sepsis occurs most frequently from the navel

CHOREA

Read in the Section on Diseases of Children at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5-8 1896

BY HENRY HATCH, M D
QUINCY ILL

In discussing the subject of chorea I am well aware that it may, at first thought, seem a dry subject to you But in bringing up this subject it is that I may awaken new life, and bring forth new ideas, and thereby get a more tangible and satisfactory understanding of the etiology and pathology of this very troublesome disease Troublesome, not alone to the patient and friends, but troublesome as well to the physician, on account of the tenacity with which it holds to its victim No disease causes more anxiety than this disease, chorea, for it is often hard to convince an anxious mother, when her child is never still on account of the violent nervous movements and excessive agitations, that it is not very ill, and that you do not expect a serious outcome

To launch out in a new channel may cause you to exclaim, mentally, "Another needless exploring expedition setting out on the pathless sea of chorea," with no definite port in view, and with an uncertainty regarding the existence of such a haven

Chorea has been and is one of the pathologic dumping grounds of the medical world, and many a man has spent tireless hours in medical research, to find a remedy which will relieve this troublesome disorder In this space the theorist throws his theory the pathologist his odds and ends, the moralist adds a few of his trite sayings and as a result there is a stupendous wilderness of unknown depth and uncertain quantity No one has penetrated successfully this wilderness many have tried, and if no other good has been done, the ground has been almost covered with their failures, so that before long we will be able to traverse the entire field by passing from one failure to another Each man can go a little farther than his predecessor, by using as stepping stones the perished efforts of those who have gone before

The term chorea, coming from the Greek word chorea, meaning a dance, has been handed down from the middle ages About the fifteenth century England was overrun with dancing, or shaking fanatics, many of whom were sent to prison, as having the devil within them People of seemingly deep religious desires and tendencies were afflicted, for they looked upon it as an affliction and a direct visitation for sins, with an unaccountable dancing, jerking, shaking, or muscle tremor of some sort, this was purely psychic During the fifteenth century the city of Strasburg had so much of the trouble that the magistrates ordered the afflicted ones to the chapel of Saint Vitus, to do penance, and to pray for relief Here is where the term "St Vitus dance" probably originated It may be of interest to us that St Vitus was a Sicilian, and a pupil of St Modestus, both suffering martyrdom as Christians under the persecutions of Diocletian, in the year three hundred, thus gaining their canonization St Vitus, however, does not hold the undisputed claim to the name of the disease, for in other parts of Europe it is known as "St Modestus' dance," "St John's dance" and "St Anthony's dance" Each saint was supposed to have curative measures in his keeping Many other terms have, at various times been applied to it One old author speaks of it as melancholia saltans saltare meaning "to dance" Another as paralysis vacillans Another as ballismus from the word signifying "to leap" Again it is known as epilepsia saltatoria as orchestromania, or the dancing madness These terms all relate to the psychic disturbances of hysteric character

Chorea proper, or Sydenham's chorea, is the disease as we recognize it to-day, while the Germans make two classes of it—chorea minor (our chorea) and chorea magna, hysteric manifestations, some of which simulate true chorea

The disease is preeminently one of early life Dr Stephen Mackenzie has a record of 439 cases with the following percentages Thirty-four per cent developed between the ages of 5 and 10 years forty-three per cent between 10 and 15, sixteen per cent between 15 and 20 years, with the largest general percentage for the thirteenth year Sée reports 513 cases, and 453 of them between the ages of 6 and 15 Sinkler 282 cases, with 217 of them between 6 and 15 years of age There is on record one case in a patient 78 years old My own experience gives me a record of forty-six cases, the oldest of which was 40 years, and a man Most of my cases have been before the period of the seventeenth year and almost all of them have been females The records of the same authors show that chorea, while a disease of early life is most frequently a disease of early female life, as my own experience has shown It follows closely or closely precedes the puberal epoch in the girl Gower who has made a deep study of the subject and who has a record of *more than one thousand* cases gives but 315 cases found in the male Sa[illegible] h l [illegible] t of seve[illegible] cases, found twenty-one [illegible] the [illegible] finely balanced nervous organization of the girl, brought up as she is, more of a hot-house plant than her brother, leading a sedentary life and under very artificial surroundings, forced to exert a growing and naturally irritable nervous system by close application to books and music, this, I say, may account for the preponderance of the statistics for the female

Chorea is one link of the chain of hereditary troubles It is the experience of many authors, and has been the result of my own observation, that alcoholism is a very prominent factor in the production of chorea Especially so when a woman becomes impregnated by her husband when in a drunken debauch Morphinism and pulmonary tuberculosis, by transmitting vitiated constitutions, are also prime factors in the production of this disease Epilepsy or migraine is frequently found in the parent of a choreic child We can not say, properly speaking, that chorea is inherited, but we can say that either its vitiated constitution is inherited from a parentage which is not healthy or that it has a choreic tendency These are hereditary land-marks The diminished vigor, the inactive cell structure, the nucleus and nucleolus burdened with inanition are tissues prematurely old. And how often have we seen children born that are young in years, but carrying the prematurely old constitution! It is a disease that believes the old adage that "Blood is thicker than water" Arising perhaps from one ancestor, say a maternal grandmother, who may have had a clear history so far as ascertained, it manifests itself in one or more members of the family, usually choosing the one whose nervous organization most closely resembles that of the ancestor, a lasting heritage from generation to generation

It is not necessarily a racial affection While some writers claim exemption for the American Indian, their claims are not substantiated, and we must admit that chorea is like the rain from heaven, falling upon the Jew and the Gentile, the just and the unjust, the rich and the poor Weir Mitchell claims relative immunity for the Negro race, and so far as my personal experience goes, having come in contact more or less with the Negro race, both in hospital and private practice, I have never seen a Negro afflicted with this disease or anything which had a semblance to it, but Sinkler reports several cases among the colored people While both the Negro and the Indian have been subject to a tremendous strain for generations, it has been a physical rather than a nervous or mental strain And it is usually people of the higher and more sensitive nervous organizations that have this disease among them What is not conducive to the production of this disease is the fact that the Indian and the Negro live a rugged, out door life Climate and climatic influences can not be said to give much light upon the subject Season of the year is also an obscure factor, if a factor at all Rainy, oppressive days are more favorable to the development of the disease than bright, sunshiny ones, if there is already a predisposition toward the disease It has been my experience that most of my cases have come to me in the latter part of the winter Most of them have been school children, and I could often understand why they were afflicted with the disease They were the offspring of parents of a highly nervous organization, who were anxious that their children should appear well in public, and many of them had instilled into the minds of their children the idea that they must be at the head of their classes Take into consideration our modern system of forced education among children, the child must go to dancing school, take music, have five or six studies, and then they all have their little parties, keeping them out late at night Is it any wonder that many of these poor children succumb under the burdens their parents press upon them? Even children are subject to blues, and disagreeable days are bad for that ailment I have not forgotten my own many despondent and blue days when I was a child, when things did not go right All are too prone to forget that we were once children ourselves, and are therefore not apt to give children enough sympathy in their little troubles

According to authorities which I have looked over, March gives the highest monthly percentage of cases and this corroborates my own observation The greatest number of cases in a given locality will arise at the season in which the greatest mental or nervous strain is put upon the children, and in our present system of civilization the spring months, when the child is anticipating its final examination, is usually the period when it has the greatest strain

Concerning the true etiology of this disease there are many theories The ancients believed that the afflicted person had a devil, and efforts were put forth to exorcise the malignant spirit They made vows, did penance, went on pilgrimages, and were doubtless benefited in so much as may arise from a fashionable method of treatment, of to-day, known as suggestion These pilgrimages also were beneficial in themselves, from the fact that the people who made them got more out-door exercise, consequently more fresh air and less nervous tension

The definition given of this disease by Sydenham in 1686 is very interesting "St Vitus dance is a sort of convulsion which takes boys and girls from the tenth year until they have done growing At first it shows itself in a shaking or unsteady movement of one of the legs, which the patient drags Then it is seen in the hand of the same side, which the patient can not keep a moment in its place, when it lies upon its breast or any part of his body If any vessel filled with drink be put in his hand, before it reaches his mouth he will exhibit a thousand gesticulations like a mountebank, and on this account, if he is associated with other children, he becomes the mark of derision, which is always detrimental to his condition He may hold the cup out straight, as if to move it to his mouth, but has his hand carried elsewhere by sudden jerks Then perhaps he contrives to bring it to his mouth If so, he will drink the liquor off at a gulp, just as if he were trying to amuse the spectators by his antics, or was afraid he would not get the water, or fluid, if he did not drink it hastily Now this affliction arises from some humor, falling on the nerves, and such irritation causes the spasm"

Not an entirely lucid definition, but with all the wealth of medical knowledge gathered from then until now, we are forced to confess it is about as good as the one of to-day It was said in the history of the disease that many causes were assigned for chorea Age, sex, race, seasons, contagion by imitation, no doubt have each some effect on the origin of the affliction Sinkler reports a case in which a trauma seemed to be the cause Others attribute the development of the disease to some reflex irritation, phymosis, intestinal parasites, pharyngitis, eczema, urticaria, eye-strain menstrual changes, etc While it can not be definitely said that any one of these is the cause of chorea, it is self-evident that any one of them may place the little patient in a more favorable condition for its development Many authorities attribute the eye symptoms to chorea, and not chorea to the eye-strain There is, however, a disease with which chorea goes hand in hand—arthritis One might say that the excessive motions which we find in chorea could be the cause of this condition One author says that in five cases of arthritis you will find one case of chorea It has either been my fortune or misfortune not to have this complication to any great extent The same author says in five cases of chorea you will see three of rheumatism One cause of the rheumatic disorder is the fact that it is difficult to keep choreic patients in suitable surroundings, on account of their nervous agitation Copeland, an English writer, says, too, that the rheumatism when associated with chorea, has a marked tendency to leave the joints and extremities and to attack fibroserous membranes, as the pericardium and cerebrospinal envelopes Another author (Rogers) goes so far as to declare that it is his belief that articular rheumatism, endocarditis and chorea are simply three phases of one and the same disease, while Osler states emphatically that there is no known disease in which endocarditis is found so constantly, postmortem, as chorea

I do not think it is fair, when we make a postmortem of a patient and find endocarditis, pericarditis, or any other "itis" in a patient who has had chorea to say that death was the result of the latter disease Is it not better to say that on account of deficient vitality or a vitiated constitution, the child became a victim of chorea, which so debilitated the constitution that it became an easy prey to the more severe disease, endocarditis or pericarditis, etc, and that death, instead of being the result of chorea, was produced by a disease, or diseases that follow in its train, as the indirect result of the deficient vitality or vitiated constitution On the other hand, it is usually acknowledged that where both arthritis and chorea are present the arthritic symptoms appear first Hirst says there is a common toxic product, which if it affects the cortex, produces chorea How Hirst has been able to ascertain this I do not know, because it is seldom, and I believe never, the case where a postmortem has been made, that the patient has died from plain, uncomplicated chorea Hirst further says if it turn its attention to the joint surfaces, there is a rheumatism This theory presupposes a locus minoris resistentiæ Sachs believes that in 33 per cent of cases either endocarditis or myocarditis precedes the chorea, and in about the same proportion of cases is found an organic lesion, usually a mitral systolic, while in a great proportion of the cases is heard an anemic murmur, which usually disappears with the chorea

Among the causes assigned for chorea is pregnancy of the early months, and a pregnant woman who has had a previous attack is especially liable to a recurrence at this period On the other hand, I have seen women who had attacks of chorea very much benefited by pregnancy and the resultant childbirth Among other cases may be mentioned the exanthemata and anemia Anemia is found in all cases of chorea, which clearly shows mal-nutrition But it is rational to think that the anemia is merely a step in the causal relation, and not an original factor Anemia may be called a reasonable factor in many cases, for if a child is well nourished with good, healthy, rich blood, I believe it is impossible for it to have chorea Chorea has also been observed to follow the toxic use of many medicinal preparations, notably the poisoning which some times follows the use of iodoform This is brought about by the fact that drugs of this character have to bear on the red corpuscular element of the blood

Chorea has been observed as an intercurrent with nearly all the more common diseases

Even more intricate and diappointing than the etiology of the disease, is the pathology One unfortunate circumstance in the state of the pathology of this disease is the fact that it is very doubtful and improbable that any case of simple, uncomplicated chorea ever died, and so-called cases of choreic death have not been produced by the chorea proper, but by some complication

Chorea, like hysteria (to which I believe it is closly related), in the first stages is assigned to want of nervous equilibrium due to diminished nutrition, which results in nervous congestion, brought on by overwork or excitability And if we could always have the cases in this first stage, I believe all could be guarded against complications, and be cured

The varied pathologic conditions reported as found in choreic patients, and given as causes for chorea, or results of chorea, form a public confession of our ignorance regarding the subject Its microbe has been earnestly sought for, but the search has produced nothing but disappointment Pianese and Dana each declares that he has discovered the bacillus, which when cultivated gives ptomains, and the injection of this substances causes chorea Pianese substantiates his claim to some extent, but his microbe is not yet accepted The staphylococcus pyogenes aureus is frequently found in the endocarditic vegetations of the choreic patient, and in one instance has been found in the blood That there is a microbe scarcely admits a doubt, as the endocarditis, pericarditis, arthritis, and sometimes septic thrombi, peritonitis, pleurisy, pneumonia and other afflictions, diseases due to direct microbic infection, or to the absorption of ptomains, clearly prove, for these diseases are the comites of chorea Postmortem pathology in chorea shows that this chorea microbe, or microbes (for there may be two or more varieties working in harmony, as may be seen in combined scarlet fever and diphtheria, and in this way account for the frequency of the intercurrent afflictions) gives its attention to the structures of the nervous system, and here the pathologic conditions are so varied and so numerous, that it is difficult to select the one for which the chorea is responsible, and find the one due to some intercurrent disease Hence there have been found hemorrhagic infracts in the lenticular nucleus, cerebral hyperemia and edema, and the same condition in the cord, vacuolization of the nerve cells and nerve trunks as in syringomyelia and hydromyelia hyalin degeneration of cells in cortex and basal ganglia, the motor cells hyperplasia of neuroglia, the expected result in chronic chorea, and a condition which remains after recovery from the disease Starr thinks that where mental symptoms predominate, the cortex is the seat of the degenerative process and that when the symptoms are chiefly muscular that the lesion is cerebral There has also been found an [illegible] diffu tion of cellular elements of the cord into the adventitia of the blood vessels supplying that structure, or pathologic karyokinesis It is of interest to note that the favorite seat of the pathologic lesion is in the corpora striata

In comparison with the definition of Sydenham let me give a modern one that of Dickenson "An unnatural hyperemia of the nerve centers, not due to any mechanical exertions but produced by causes, mainly of two kinds One, a morbid influence which may affect the nerve centers, as it affects their organs and tissues The other condition is usually mental, but sometimes what is called reflex, which especially belongs to, and disturbs the nervous system, and affects persons differently, according to the inherited morbidity of their natures"

Having discussed the natural history, etiology and pathology of chorea in a rather hasty manner we now come to the treatment, and in my opinion every case of pure chorea should be cured, and especially so if we can have fairly good surroundings, with fairly sensible people to take care of the patient It does not require wealth nor any great ability for the nursing of this class of patients, but it does require a good physician, who thoroughly understands the special constitutional condition of his patient, and understands the results and the action that he may obtain from the drugs which he will use First the patient with chorea ought not to be excited by much company, and if it is a child it should not be associated with other children, from the fact that children, seeing the constant nervous, and apparently senseless movements, of their companion are very apt to laugh and make fun of him, or her, and consequently destroy what little confidence the patient may have in its ability to control its movements The patient should be kept clean, should be frequently bathed, well rubbed after each bath, and be placed with cheerful, happy people His surroundings and companions should be restful If it is an exceedingly bad case the patient should be kept in bed as much as possible, and if the motions are violent to the extent that he bruises himself, it is also well to put on a jacket by which you can fasten his hands Massage treatment is very beneficial in these cases If the child is anemic he should have iron If he is poorly nourished, and does not eat enough food, he should have cod-liver oil If he comes from syphilitic or tubercular parentage, his treatment should be directed to these peculiar points All sorts of remedies have been recommended for the treatment of this disease (Shoemaker forty-seven, Bartholow seventeen) Arsenic, zinc compounds, cimicifuga, antipyrin, chloral, sulphur, quinin in large doses, opium, digitalis, and I might mention a host of other remedies, but it is unnecessary Then as toward treatment during the changes in action If in pain, plasters In endocarditis, potassium chlorid Now all these remedies may be well in their places, but there is one remedy upon which I place my greatest faith, and that is strychnin I have given it so much that I have come to look upon this drug as a specific in the treatment of this disease, and no matter what complications I may find, I treat each complication and hold fast to my strychnin I give it about every four hours, beginning with the one hundred and twentieth of a grain, and gradually reaching one-sixth, and then continue it for an indefinite period, or until my patient gets well In connection with that I give digitalis, or iron or cod-liver oil, or salsoda where indicated, and if my patient is very restless, and he needs rest I give chloral, potassium bromid, morphin and sulfonal, as I think best for each special patient

And now as to the prognosis of this disease I believe that every case of pure chorea should, and can, be cured If you will study the peculiarity of your patient, and follow the remedies as indicated in this paper, if you can control the parents, you can absolutely say when a case of chorea is brought to you, that it will surely be cured

---

MAN'S BRAIN AND MIND

THE FORMER SOMETIMES INSANE, THE LATTER NEVER

Read in the Section on Neurology and Medical Jurisprudence at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga May 5-8 1896

BY G W DRAKE, M D

CHATTANOOGA TENN

Man's brain is the storage battery of energy, the seat of consciousness and the organ of the mind From it are transmitted by nerve fibers, energy for the functional activity of all organs and the vital metabolism of all tissue cells In it are localized areas for the reception of energy and the perception of sensations

A sane brain is one in which all its cells and cell derivatives, fibers and other material substances are in a normal condition chemically, physically and vitally

Chemic analysis of the different parts of the brain is not alone sufficient to enable the neurologist to judge of its sanity, nor is a microscopic examination adequate Because neither will reveal the relative position of molecules in a cell or atoms in a molecule, upon which in my opinion the normal function of the parts depends, as also the kind, number and shape of the molecules, together with their atomic structure When the cerebral centers are in a normal condition, the brain is sane, otherwise it is insane When the dominating brain centers which supply functional energy to the various organs and tissues of the body are not perfectly sane there can not be perfect function None of these centers are in a condition of perfect sanity and there is no organ or tissue that is perfectly healthy in function The consequence is that the period of activity of every tissue is limited and it can not exist perpetually It must sooner or later cease to manifest life, dissolve into its original elements and return to the dominion of chemic energy, as the dust of the earth This is the common lot of all vital tissues The source of their vital energy is finite, and they are consequently doomed to inevitable exhaustion

Passing from the involuntary centers of the brain we come to consider the centers of conscious sensation, the habitat of consciousness

Man is a triune being, consisting of a material, a sensible and an intellectual ego These parts are usually denominated, body, spirit and mind Contrary to the doctrine of the scientific Christian and that of the christian scientist, I do not believe in the existence of mental diseases, nor diseases of the sensible ego Disease, I believe to be a disarrangement of the normal arrangement of matter in the structure of one or more cells of the body The gravity of the symptoms depends on the locality and the number of the cells affected So-called "functional diseases," all have a material cause, whether the physician can find it or not So long as the material structure is normal the functional activity will be normal The sensible ego, or consciousness, is always ready to exercise its faculties in the various brain centers of sensation where it is situated, viz, those of hearing, feeling, tasting, seeing and smelling The peripheral and central organs of the five senses must be in health in order that the sensations may become conscious of normal impressions All the cerebral centers of the special senses are more or less insane, and there does not exist perfect vision perfect hearing or perfection of any of the sensations Everybody is color blind to a degree, and there is a degree of imperfection in all the senses owing to material disturbances There is a material basis for every pain and every subjective symptom of disease or discomfort The sooner physicians recognize this fact and bring to bear their materia medica on all material disturbances, the better for the patient Let not christian science, spiritualism, faith cure and other kindred humbugs lead astray the grand old profession of scientific medicine The best brains of our best doctors are to be relied on as bulwarks of defense against the cunning novelties which are attempted to be introduced into therapeutics Suggestion and hypnotism as therapeutic agents can be effective *only* as the *material* structures, the seat of the diseases, are responsive to their action Imaginary diseases are real material images and should be treated as such The intelligent physician should search diligently for the concealed picture before attempting to efface it Therapeusis based on mistaken diagnosis may lead to disastrous results It is possible thus to make a diseased image where one did not previously exist Insanity of the intellectual centers of the brain is the form usually denominated mental insanity, and its subjective symptomatology can be learned by studying that of the so-called "mental diseases" The function of these centers is to manifest the faculties of the mind, and it is essential that they be in perfect order to make a perfect reflex of mental action Any derangement of matter or departure from the normal standard more or less unfits these organs of the mind for their physiologic work Every case of insanity should be carefully studied etiologically, with the view of cerebral localization of the seat of diseased tissue After the discovery of the part affected, a rational materia medical course of treatment should be instituted in conjunction with suitable hygienic environment Disarranged brain substance in the intellectual centers can not make a correct manifestation of the faculties of the mind Brain culture as a physical science has not hitherto received the attention which its importance demands The cerebral centers for special senses, together with those for the higher faculties of the mind should be duly exercised for the purpose of enhancing their capacity By systematic physical culture of these centers the equilibrium of the brain may be maintained, and in this way insanity be prevented in many cases Brain sanitation is conducive to sanity, and I may here interject that watering the brain copiously is a measure of great hygienic value as well as an essential therapeutic procedure Water the sick of all diseases, but especially those sick of insanity

I pass to a brief consideration of man's mind This is the the terra incognita of the anatomist and will ever continue so, for it's not of the earth, earthy Mind is a general entity, specialized in man and individualized in a particular man Man's mind is the first person of the human "trinity" and is made in the likeness of the first person of the divine trinity It is the supervisor and supreme director of the material man The brain is its organ, but its habitat is unknown It may dwell in some localized area or it may be ubiquitous The minds of all men I believe to be equal, but there is great diversity in the structures of the brains or mind organs of different individuals The mind of the fool or idiot is equal to that of the most brilliant philosopher The mind of the newborn babe is equal to that of the full-grown adult There is, however, a marked difference in the manifestations of mental action in different classes of human beings, owing to the difference in the material composition of their brain centers These brain centers may be cultivated and developed by use They may be brought nearer and nearer to perfection and become better organs of the perfect mind The mind does not develop or deteriorate The nearer the mental cerebral centers approach perfection, the grander their *manifestations* of the *conceptions* of the *mind* The farther they fall below the normal standard the feebler they portray the mental faculties and the more imbecile their individual possessors Great thinkers are all men, young and old, ignorant and educated, sane and insane or idiots, but great also is the difference of the brain impression of their thoughts

The mind is never insane It belongs to that class of imponderable agents or energies which was created perfect in the beginning It requires a certain adjustment of matter for its manifestation, and the better this adjustment the better the manifestation

There can be no change in the mind, but only in its mode of action through a change in the cerebral apparatus Defective machinery makes imperfect movement however perfect the motive power Electricity is the same, whether it turns a simple wheel or is applied by suitable adjustment to the most complicated mechanical contrivance It is no more and no less electricity whether it runs the street car or the wheel of the fanning machine It never gets out of order and never needs repair So with the mind, its brain machine may break down and need adjusting, but the mind can not be injured by traumatism, autointoxication or bacterial toxins It can not be pierced by the bullet or cut in twain by the knife, it fears no evil from without, its only concern is for its fellow entity, the body, from which it must sooner or later be separated The body will crumble away and return to the dust as it *was* and the spirit to 'God who gave it, but the mind will roam about in the unseen universe and wait for the resurrection of the body After the resurrection, the mind will preside over a perfect body and spirit, and redeemed man will be a perfect triune being in the image of the Triune God *Cerebrum sanum in corpore sano* is all that is needed to complete the perfect man The *mens sana* needs not a physician Brain culture should constitute a prominent department of physical culture Brain development should not be neglected in the present craze for muscle training A systematic *curriculum* of exercises should be arranged for training every sense organ with reference to its better education The courses in music, painting, sculpture, etc should be studied with reference to their importance in brain culture Every sound every picture every form every muscular movement makes its image on the brain and contributes to its development The brain is the highest organ of the body in position and importance In it mind, spirit and matter meet to form the triune man in the image of the Triune God There is no difference in the members of the human family, Hottentot, Mongolian or European, as to their minds, the difference is only in the structure of their brains After death and the resurrection all the redeemed of Adam's race will be equal

Often on the thoroughfares of crowded cities, in the parlors of the devotees of fashion, in the offices of money dealers and in the haunts of the busy fortune hunters, I have tried to imagine the appearance of the brain structures of the different types of the *homo genus* and compare one with another Shape of head, contour of face and form of features furnish a slight index to the hidden form and individual structure of the brain The behavior of the individual is the best criterion of the sanity or insanity of his mind organ The conduct of every individual must be compared with that of the highest type of man and his brain can be graded thereby with accurate precision

Faces may deceive, pomp of wealth or foible of fashion may conceal, but truth will out and show by character the inwardness of the brain The brainiest men are those whose habits of life are nearest perfection The world is full of deformed brains

A NOTE ON THE PATHOMENTAL EFFECTS OF DEGENERATIVE HABIT

Read in the Section on Neurology and Medical Jurisprudence at the Forty Seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5-8 1896

BY H S DRAYTON, M D , LL B

NEW YORK

In his play, "Two Gentlemen of Verona," Shakespeare makes Valentine say—

> "How use doth breed a habit in a man "

In this remark we have an expression of psychological truth, that three centuries of later observation has not been able to gainsay The disciples of heredity have availed themselves of the apparent effects of habit impression in formulating their creed, employing them as evidence of a double meaning, especially if they were of a degenerate nature "Evidence here," they would say, "of congenital predisposition, to think and act in lines that enfeeble mind and pervert body " The pessimistic speculations of a Schopenhauer or a Nordau may echo the opinions of medieval prophets of a fate-bound destiny, and find a hearing in a certain class, but the cheerful, sunlit view of a better future for him who seeks it earnestly is finding a larger recognition among the sober and thoughtful year by year In the field of anthropology there does not appear that tenacious insistence upon the preeminent influence of heredity that characterized the discussions of ten years ago Manouvrier, Brouardel, Magnan, and others of authority refuse to admit the existence of any distinctive type of nervous organism for the vice-bound and criminal, and contend that it is not so much the inheritance of a disposition toward conduct of an irregular, vicious nature as it is the social relation into which one is born or in which he lives, *le milieu*, that should receive consideration, when we commence to trace the etiology of moral perversion and crime In the Paris Congress of 1889 M Manouvrier argued with great force upon the principle that the commission of acts in violation of law did not demonstrate a morbid type of constitution but rather a certain caste of temperament and unfortunate surroundings

Dr Henry Maudsley, once a pronounced apostle of heredity of the severer class, said lately in answer to the question "Is a man hopelessly chained down by the weight of his inheritance?" "By no means, for there is something else besides inheritance that makes fate, and that is education It is a physiologic law that the brain throughout infancy, childhood and youth grows to the circumstances with which it is placed, and therefore the actual development of a brain may be as much influenced by the kind of nutriment supplied to it as long as it grows "

The verdict of psychology is substantially in keeping with that of physiology Sully, for example, in "Handbook of Psychology," writes "In the present state of knowledge heredity only helps to account for comparatively few among the host of peculiarities that go to make up the natural phases of individual character External influences cause variations No two are subject to the same influences The school, the circle of friends, the business, etc , differentiate minds The body takes on a form of growth because of the special line of habit in eating, exercising, etc , of the individual So the mind grows on what it is fed in the daily life Lines of mental growth will be to some extent predetermined by innate capabilities and tendencies, but these only partly limit the process, they do not fix its precise character The particular ideas and connections of ideas that form the intellectual habits fix the peculiar coloring of the feelings and the special lines of conduct will all be determined by the character of the surroundings " A particular trend of thought now becoming popular in educational circles is derived from a philosopher of a century ago, Herbart and which accentuates in stronger terms than those of Sully the effect of education According to Herbartian pedagogies children have at first no real moral character but acquire it through the union or association of acts of will that have a moral quality It is the business of training to bring all classes of will action under the dominion of moral maxims in order that "a symmetrical passion for good" may be created Thus it is clear that in the Herbartian doctrine it is the tone and quality of the general habits that determine the character, and these habits are not fortuitous, or predetermined by birth

As to the effect of habits, however acquired, it is undeniable that they produce in time conditions of mind and body that in themselves reflect a healthful or injurious nature Are the habits of a vicious kind? Persisted in they accomplish alterations in the substance and relations of the cerebro-spinal organism that are abnormal and degenerate Thus the soil of mind becomes more appropriate for the generation of evil fruit than for good The benign elements become feeble and uninfluential or so perverted that their response to suggestions of a vicious sort contributes to moral disorder

The studies of the cerebralist have shown that the form and constitution of the brain bear a particular relation to mind capacity and character We know that certain endowments of structure render one more susceptible to the adoption of manners and habits of a coarse and perverting nature Benedikt, Lombroso, Maudsley, Spitzka, H Mann, Allen, Buttolph, etc , have discussed the characteristics of structure that may dispose a man in certain relations of suggestion to respond to impulses of an unlawful kind Dr Maudsley remarks, "All broad-headed people are very selfish, that is, all who have the head broad in proportion to its length An undue preponderance of the breadth of the head throughout the region in which they (the phrenologists) place the propensities indicates with certainty an animal self-love which can scarcely be trusted at all times to adopt only fair means for its gratification " The London professor, arguing from the relation of the anterior brain lobes to intellect further remarks, "The bad features of a badly formed head would include a narrowness and lowness of the forehead, a flatness of the upper part of the head, a bulging of the sides toward the base and a great development of the lower and posterior part, with these grievous characters might be associated, a wideness of the zygomatic arch, as in the carnivorous animal, and massive jaws " Such a development of brain intimates the possession by nature of strong animal instincts, and a comparatively weak endowment of those sentiments that inspire kindness, sympathy and deference Upon such a stock it were easy to graft habits of a vicious sort through exposure to surroundings that are degraded and brutal

Thought habit then has its coördinate factors in the cerebral substance, where molecular changes are produced with facility and effect correspondent to the duration of the habit Repetition operates not only to render these molecular changes more rapid and easy, but is productive of growth of nerve substance of a special sort, an evolution correlative to the habit acquired The motor areas of a trained artisan are more extensively furnished with appropriate cells than those of an office clerk The use of hand and arm stimulate action and consequent cell proliferation in the anterior and posterior ascending convolutions The artist develops those centers of form and color that are of daily employment in his profession and they become noticeably marked in his cranial physiognomy Professor Gates of Chicago experiments on the color sense of dogs and proves that the enforced exercise of that sense for a period had a result in decided increase of brain tissue in the color area

Conversely, disease of mind faculty is attended with declension and disease of the cell elements of the coordinate center and decline in strength Any habit, therefore, that inhibits or suppresses the activity of an important intellectnal or moral faculty disturbs the mental balance and impairs the integrity of judgment in no trifling degree This impairment if not compensated will go on until pronounced insanity results Interference with the normal function of any physiologic organ continued or frequently repeated causes deterioration of that organ and of its cerebral center of nervous supply This deterioration implies either functional decline or positive disease of the reciprocal parts Habits that contribute to the maintenance of health oppose tendencies to disease, of whatever nature the disease may be The late Sir James Coxe, in his enumeration of the six leading causes of physical deterioration that may eventuate in insanity, places "dissipation of various forms" first, because habits of dissipation affect the nervous system more directly and certainly than other causes The specially conspicuous of these habits are Alcoholism, the use of tobacco and opiates The disturbances of function wrought by the practice of taking alcoholic beverages daily belong to our common stock of knowledge and represent generally or analogously what of nerve injury is done by toxic narcotics as a class They depress the vital tone of every organ of the body Of alcohol we know that its high diffusible quality enables it to penetrate the animal tissues in every direction, and by impairing the nutritive properties of the blood to interfere with those metabolic changes that are essential to the maintenance of the integrity and vigor of every organ, muscle, nerve gland, mucosa, lymphatic etc , all suffer deterioration from frequent contact with it We know well its ravages on stomach, kidney heart and liver, and its inhibitive effects upon the cerebral and spinal centers are matters of every day observation It may be that Hyrtl more than merely accentuated his impressions from laboratory examination when he said that he could easily detect the brain of a drunkard in the dark because of its comparative hardness but we certainly should expect a similar effect upon the nerve mass whether it were placed in alcohol to soak, or the latter instilled by daily installments The impairment of the functional energy is so reflected in the character and conduct of the habitué that we are irresistibly led to the conclusion that the disturbances of the nervous centers are those with which the higher psychical faculties of mind are directly concerned These no longer exert their normal control in the intellectual and moral expression, and weakness of will and instability of judgment advance *pari passu* with the alcoholic invasion

It is not claimed that alcohol has a *specific* effect upon certain brain parts, and attacks them on opportunity, but that by perversion of the nutritive supply it as an early effect lowers the functional tone of the brain, and these may introduce a train of evil consequences to motor and psychic action The senses, which at first may be exalted through inhibition of vaso-motor control, become later obtunded, the intellectual perception relatively declines, and with this power to reflect and to appreciate nice distinctions is lost The sentiments of courtesy, refinement and kindness, esteem of virtuous character, independence and manly resolve become less and less exhibited, until quite replaced by indifference to the commonest usages and requirements of propriety and duty The character assumes more and more a pathologic form We have the exhibition finally of a mental lesion, as insanity, whose physical concomitants of perverted function offer material for an easy diagnosis The alcoholic invasion especially affects the higher organic centers of the brain, those that correlate moral apperception, because of their more delicate adjustment to the economy of nutrition and sympathetic impression Then, too, their comparative remoteness from the arterial centers may be another reason for their disturbance Grief, disappointment, chagrin, poverty, may be alleged as cause for a large proportion of society's inebriates, but the fact remains that eight-tenths of the intemperate drinking that abounds is begun in the home or the friendly circle by indulgence of the appetite in ways imprudent or vicious As Dr Bushnell once said The scale and order of simplicity once broken, then ensues a distempered or distemperate life that runs more certainly to that which is intemperate

The cocain, opium and other drug habits of our day may run a shorter course than that of the alcoholic but their perverting effects are not more certain or disastrous A similarly associated impairment of the physical and mental organisms is the outcome, a similar change of function, from capacity to incapacity, from strength to impotence from probity to dishonesty, from nobility to vileness from humanity to bestiality These are pathomental artefacts of an uncontrolled self-indulgence Now that we have the *dictum* of the French pathologists at command to supplement our own observations, we know that the habit of smoking operates to produce changes in the blood and the tissues through cardiac irritation and gastric derangement, changes that in time necessarily lower the general vital tone, and affect unhappily the economy of mind The pessimism and dyspepsia of Carlyle were correlative What of his inveterate pipe smoking and his almost equally inveterate indulgence in stomach-trying diet? How the fine cells of that powerful brain must have suffered from the scanty nutritive supply that a vitiated blood stream brought to them! We can easily imagine that the blood of the author of that story of the French Revolution so luridly picturesque in its narration of horror must have bristled in the microscope with its billions of crenated corpuscles The eccentric vision of the historian and the distempered conduct of the man as husband and acquaintance furnish a homily for the moralist, and a fertile study for the neurologist

The successful treatment of the chronic habitué involves as a primary object the readjustment of the factors of his thought life, so that his motives for right and orderly living shall be renewed and his will inspired with energy and persistence But we shall fail to restore coherence and harmony in his psychic relations if we do not in the outset attend to the rebuilding of his body, awakening to fresh activity the organic functions, so that the nervous correlates of mind—cell and fiber—shall be supplied with the elements essential to their reinvestment, and this reinvestment should go on in advance of psychic reformation in order that the intelligence of the man shall be conscious of a growing strength The older the habit the more difficult its management, yet it is the age of the habitué that has more to do with the determination of curability Who, however, will say that the degenerative changes in a given case have gone so far that no improvement is possible? Those whose experience warrants an expression of judgment are inclined to take encouraging views of the effect of considerate treatment The President of this section, after years of critical observation, has said "The tendency in nature being toward the maintenance of the perfect type, we may look for an endowment of new normal tissue where all the conditions are favorable, and under such circumstances a cure, or what is popularly called reformation, takes place"

Each case must be studied by itself, the type of constitution being understood, the stage of degeneration may be approximated, and a forecast of the probable outcome of systematic treatment be ventured

DISCUSSION ON PAPERS OF DRS DRAKE AND DRAYTON

Dr Charles H Hughes—The first paper seems to take a rather peculiar position The term mental disease, as applied to insanity, and as a synonym for insanity, has been understood by alienists and psychiatrists in all countries to be a conventional term Science has assumed that mind is the aggregate of the personality and individuality of the person, as discerned through the several functions of the brain and cerebro spinal axis It has never entered into the metaphysical question as to what is mind Nor has it attempted to fathom the nature of the cell Psychologic science has relegated the question of the nature and essence of mind to the unknowable The Cartesian philosophers maintained that the mind resided in the whole and in every part of the organism, that it represented the individuality of the person and was the psychic portraiture of his personality Science has to do with material things, its instrumentalities of research are material, and the organs which it examines with the microscope, the test tube or the crucible are material Science says that the brain is the organ of mind, adopting that term and accepting it from the psychologists The somatic psychologists study the physiology of the brain in regard to the manifestations of what philosophy has called mind Now, we have never attempted to maintain that the material entity of the psychologists could become diseased, because if it become diseased it might also die, and we know the dilemma in which we might be placed Science has judiciously evaded this question, and left it to the domain of pure psychology No sound psychiatrist, no correct alienist, who is careful of what he says, will go upon the witness stand or the rostrum and maintain that the mind can become diseased

We do not think that the brain centers preside exclusively over the material metabolism of the organism While science has reached the point at which it believes that conditions in the gray cortex have much to do with the normal metabolism of the organism, it has not reached the point at which it can say that they all reside there, for we know that acephalous beings have the power of physiologic metabolism in their ganglionic processes, that hearts are formed, livers developed, kidneys evolved, etc, without the intervention of the higher psychic centers of the cerebrum While, in the main, the object of the paper would meet with the concurrence of most men who have made this a life long study, still I think it has somewhat trespassed beyond the domain of science

Dr Burr—It seems unnecessary for us to go into matters in connection with the soul, the spirit

The subject of autointoxication I consider of great importance to those who are treating insane conditions I find myself confronted with difficulties in the way of medicating those cases ordinarily They have symptoms which I would like to meet by medicine directed to the condition, but the objection of the patient is very difficult to counteract

As I have always understood the term hypochondriasis, it signifies a willful lack of interest in one's self, and I am satisfied that in the majority of cases of hypochondriasis there is at the bottom a pathologic condition, and often this condition of autointoxication, owing to trouble with the kidneys, the intestine, malassimilation and faulty metabolism

Dr Sanger Brown—The great trouble in neurology has been that we have been wanting in sufficient distinct and clear data with which to work, and I think the conception of the neuron as it has been promulgated by students in various countries in the last year or two—due mainly to the great improvements that have been made in the process of staining, and studying the primary unity of the nerves—has gone a great way toward giving the remarks which we have before made, and which have been hypotheses, an actual definite meaning

I simply wish to refer to the published results of Dr Berkeley's recent investigations in Johns Hopkins University, which were set forth some months ago in *The Brain* This only covers one department of this subject, but it is a very important one and one which I think ought to be emphasized, because it shows that it is possible we may look forward to a time when the various poisons, the auto infections, etc, can be definitely reducible to a distinct anatomic basis, indeed, that it may be possible, perhaps, to reduce insanity to this anatomic basis

Heretofore we had been forced to say that there were gross changes in alcoholism in the brain There might be sclerosis in alcoholism or there might not, I do not think it is possible to demonstrate that If two brains were laid down before us, one of the worst drunkard in the world, and one of a man who had never tasted a drop, I do not think it would be possible to differentiate between them Dr Berkeley took a large number of rabbits and fed them with all the alcohol they would stand for seven or eight months, until many of them died of convulsions He found no process of hardening on examining their brains but he did find changes in the body of the neuron —not changes in the axis cylinder This was not the result of the staining process, because he made numerous control experiments I think this indicates the direction in which we should look, because when we are studying neurology we are only studying the function of the neurons, and everything indicates that they may be regarded as so many units, and we can study the symptoms exhibited from that standpoint

Dr J T **Searcy**—I refer in my paper to changes by toxins in the neuron, a change in the shape and size of the body, this becoming shrunken, and the processes of the neuron being altered at their extremities

The changes in the axis cylinders of peripheral nerves are also noted in some conditions like the neuritis of alcohol and peripheral neuritis The whole subject is still in the beginning of its growth

Dr **Drake**—One of the strictures on my paper seems to be as to my claim that the functional activity of the centers of metabolism was dependent upon the tissues in the brain This I wish to explain, as I include in the brain everything in the cranial cavity The ganglionic centers I consider to be centers which receive their energy from these higher centers If they receive no reinforcement of energy, then the metabolism ceases, but so long as they are connected by nerve fibers with the higher centers then the process continues Cut the connection and the process continues for awhile, but as soon as the energy which is already contained in those lower centers is exhausted the metabolism ceases The heart can pulsate out of the body for awhile by virtue of the energy which is contained in its own ganglion centers As soon as that energy is expended, it ceases to beat

Dr **Kleinschmidt**, of Washington, D C – Hodges has shown very clearly the great influence exerted upon the central nerve cells by excitation of its axis cylinder process, the changes being shown in altered conditions of form, etc Again, it has been shown, over and over again, by Weigert especially, that normal excitation, if repeated through the cells of the nerve centers, have their influence upon the morphology and undoubtedly also upon the chemistry and molecular structure of the central nerve cells So that, considering the central nerve cell as the center of energy, we may readily suppose that influence such as cited by the gentleman from New York will have a very decided impression upon the central nerve cell He held that by a proper mode of educating the brain that had been reduced by disease or intoxication or bad habits, we were able to reproduce by proliferation new central nerve cells I do not believe that that process has as yet been clearly demonstrated I do not believe that the central nerve cell, and especially the higher differentiated nerve cell of the cerebral cortex, under any conditions can increase and multiply by proliferation But there is another way in which we may educate that central mechanism Taking the studies of the neuron we find that the nerve cell itself adds to its connections and the capacity of the nerve cell is entirely to be measured by the number of connections it can make with other nerve cells, bringing it into nearer connection with the center of the system in which it may be In this case proper education may lead to a new combination, to increase in the protoplasm processes by which new combinations are brought about, and in that way we gain a greater result We can not suppose that all nerve cells are equally affected and all the nerve cells in a single cortex are probably not occupied at one time Now, if we can increase the metabolism in a nerve cell to such an extent that these processes shall form into wider connections, we therefore improve that nerve cell I do not think that a cerebral cell once formed can proliferate

Dr **Charles H Hughes**—I only know of one man who ever maintained that the cerebral cortex cells could be reproduced, and that was John P Gray, of Utica The peripheral nervous system can reproduce the central nervous system I do not think in regard to the question of degeneration, that toxicity is the sole cause of mental aberration in those cases in which insanity appears I think that we are not yet prepared by any of the later researches to explode the doctrine that insanity is the product of more than one generation, that a morbid aptitude of the cell, or the neuron as we shall have to say now, and we shall have to speak of neurons, neurils, and epi neurils, in order to be in accord with the progress of modern histologic research—is one of the factors I do not think that insanity, as a rule, is primarily developed by any form of acute toxicity It is excited by it, but it resides originally in the morbid aptitude of the psychic center or cell envelope

I do not believe, however, in the degeneration of the race, that the psychic sense of the average human being is less capable of sustaining pressure, on the contrary, I believe that they are standing more than the same centers in our ancestors and that the tendency of nature is to preserve the type

> "So careful of the type she seems,
> So careless of the single germ"

Individuals fall by the wayside, unable to carry the burdens laid upon them, and failing to learn wisdom early in life

It is the pathologic condition of the center of the cell soil that gives rise to the morbid manifestation Given a certain influence that acts upon the psychic centers of one individual and his cerebrum sustains it without morbid result One individual takes alchohol in his blood, and displays no delirium, another takes opium, and displays no delirium, while the third becomes crazy drunk or markedly insane under the influence of either It is the pathologic condition of the cell that displays the aptitude of degeneracy of habit, and it is the morbid tendency which is the exciting cause

---

SARCOMA OF THE CHOROID, A SERIES OF CASES

Delivered before the Section on Ophthalmology at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5-8 1896

BY GEORGE F FISKE, M D

CHICAGO

Case 1 —M E B , architect, age 50, presented himself April 3, 1888, complaining of a cloud in the right eye which followed a severe attack of "catarrhal fever" three weeks before

O D 36 in Sph , 42 in Cyl , 90 deg 5 5 Sz
O D 48 in Sph , 18 in Cyl , 90 deg 5 6 Sz

In the left eye there were several choroidal plaques in the upper outer periphery, and floating opacities in the vitreous In the right eye separation of the retina on middle nasal side extending within 2 mm of the papilla Nothing to distinguish it from ordinary separation of the retina No suspicion of tumor

Patient gave a history of very close application and was in a highly nervous state Consultation was had with two other specialists with no thought of sarcoma Patient stopped work for two weeks, protected the eyes from light, wore a bandage and remained in bed quite constantly, with no change He then resumed his work to a certain extent, contrary to advice and did not return to the writer until June 18 when vision was reduced to perception of light, anterior chamber shallow tension plus, pain and cyclitis Diagnosis of sarcoma was made and immediate evisceration of the orbit advised Patient preferred to go to Europe, where eye was enucleated in Berlin the middle of July and proved to be a melano sarcoma patient dying within six months, result of metastases in the liver no recurrence at seat of operation

Case 2 —Mr G A , plumber, aged 40, consulted me Oct 9 1890 having noticed for five weeks that sight in the right eye was imperfect

O D 0 75 D Cyl 90 deg 5 8 Sz
O S 0 75 D Cyl 90 deg 5 5 Sz

Examination of the right eye with the ophthalmoscope revealed a small separation of the retina on nasal side showing the retina pushed forward by a small body apparently 1 mm in diameter, extending diagonally over the papilla, not quite to its center Diagnosis was made of sarcoma of choroid and immediate enucleation advised

Patient did nothing for nearly two weeks and then consulted three eminent colleagues, all of whom pronounced the separation as probably not due to a tumor, though one proposed a needle operation for purpose of diagnosis, which was refused This means that the separation had extended greatly during the two weeks, as there was no question as to the diagnosis October 9 January 19 patient again consulted a colleague, presenting iridocyclitis and a glaucomatous condition Enucleation was performed Feb 1, 1891, and a choroidal tumor of 5 mm in diameter found, of uniformly black color, composed of small spindle cells without reticulum and numerous large pigment cells Later, patient came again under my observation and remained there for six months There was no recurrence in the orbit of the sarcoma, but the patient began gradually to fail, six months after the operation, went away for his health and died within eighteen months of "liver trouble" No post mortem

Case 3 —Mrs M presented herself Sept 16, 1893, with a history of poor vision in right eye for several months Vision equals fingers in the outer field at two feet Separation of the retina involving all but the outer upper and inner upper portion of the retina Optic nerve not visible No tension and no iritis or cyclitis Media clear and the retina apparently pushed forward by a large, dark, rounded mass growing from the outer central portion of the choroid

Diagnosis Melano sarcoma, and I enucleated September 20 The tumor was round 7 mm in diameter, not extending to the papilla, composed of spindle cells, round granular and pigment cells Optic nerve showed no infiltration nor did specimens from the connective tissue of the orbit Jan 1, 1896, there had been no recurrence, patient in normal condition

Case 4 —Mr E C, merchant, aged 56, came Nov 6, 1893, with a history of poor vision in right eye since May 1893 Old corneal scar from blow with a marble at ten years of age Counts fingers at five feet Separation of the retina nearly complete, except in upper inner quadrant Ophthalmoscope reveals a mass reaching nearly to the iris in front growing from the outer upper portion of the field, covered by the retina still showing the retinal vessels Enucleation advised, with diagnosis of sarcoma of choroid I operated Nov 17, 1893, and found tumor of 4 mm diameter, having its origin 6 mm from the papilla Tumor had a very small base, was a spindle celled sarcoma with some pigment Patient's condition Jan 20, 1896, good, health excellent, with no sign of recurrence

Case 5 —Mr C K, business man, age about 48, consulted me November 28 1893, with the request that I give him a pair of glasses

O D —1 D Cyl, 160 deg 5 6 Sz Partly
O S —0 50 D Cyl, 160 deg 5 5

The day was rather dark and vision so good that it was only a fixed habit which led me to examine the fundus, when I was greatly surprised to find a small tumor on nasal side near the macula, with retina pushed forward and adherent to the tumor, no separation of the retina extending away from the base of the tumor

Diagnosis Sarcoma The patient lost a brother from carcinoma of the tongue Patient went to Brooklyn for operation at the hands of a friend who is a specialist and the eye was enucleated Dec 5, 1893

The following is the report of the pathologist at the New York Hospital "The tumor is almost spherical in shape It originated in the loose connective tissue of the suprachoroidal space and involved the entire choroidal layer and external layer of retina, pigment layer, rods and cones, mebrana limitans externa and extended a short distance on either side in the external molecular layer of the retina, the other layers of the retina are pushed before the tumor and can be recognized as a thin membrane everywhere limiting the tumor in front Posteriorly it is limited by the sclerotic, which at the point of contact with the tumor is only one half the normal thickness The tumor is 7 mm in diameter It is estimated that the center of the tumor is 5 mm from the physiologic excavation It is composed of spindle cells of medium size, spindle celled sarcoma, with a minimum amount of basement substance The vascular supply is quite abundant There are pigment granules through out, but it can not be regarded as a melanotic sarcoma Along the course of one or two of the vessels in the sclerotic coat are numerous round and spindle form cells, but can not be identified as sarcomatous elements The optic nerve, dural sheath and external sheath show no evidence of tumor tissue"

Feb 29, 1896, patient's health perfect, no sign of recurrence

There are in addition to the above five cases, of which I have been able to give more or less complete histories two cases in my record books which I have not been able to report, one where the diagnosis was quite certain and whose history I hope to give later, and another where it is a question as to whether there is a tumor under the separation of the retina or not

Of the above five cases two died, one certainly and the other probably as a result of a recurrence of the sarcoma in other parts of the body Both cases where death ensued were rapid in progress and had reached the stage of glaucoma and involvement of the ciliary body

The report is presented for the purpose of a discussion as to the practical questions which present themselves

1 The question of early diagnosis between the separation of the retina and the separation of the retina which is caused by a tumor behind it

2 The question as to whether enucleation shall be advised in cases where the diagnosis is not certain

3 The importance and duty of assisting one another by giving to each patient, in all cases of doubt, i e, in almost all cases of ablatio retinæ, full notes and sketches for use when patients consult other specialists, which is usually the case

First, as to diagnosis This is often easy when the tumor can be seen, or where glaucomatous symptoms or inflammations of the ciliary body, have presented themselves, also where the separation follows extreme myopia, or a blow, or injury, or seasickness Where the separation is slight and occurs in the upper half of the field, the tendency of the sub-retinal fluid to seek the lowest level will often assist the diagnosis, and in some cases drawing off the fluid with a hollow needle and syringe will clear up the doubt even though the separation is not cured by that means

The importance of early diagnosis is greatly increased by the fact that these choroidal sarcomas almost always occur as primary and not as metastatic sarcomas I have not found in the literature a single case of a sarcoma or melano-sarcoma occurring as a metastasis following sarcoma in some other portion of the body On the other hand, particularly in the case of melano sarcoma, metastases in other parts of the body following the sarcoma in the eye-ball are very frequent and fatal

Second, as to indications for an operation in cases of doubt, I would suggest enucleation be advised where *a*, the vision is irrevocably destroyed and there is doubt as to the presence of a tumor, *b*, where, though there is slight vision present, it is failing rapidly through extension of the separation, and there are no previous examinations by colleagues, excluding the presence of a tumor, with no good reason for excluding it from the history of the case, *c*, where glaucomatous symptoms show themselves or cyclitis or irido-cyclitis

DERMOID TUMORS OF THE CORNEA

Read in the Section on Ophthalmology, at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5-8 1896

BY ALBERT RUFUS BAKER, M D
Professor of Diseases of the Eye, Ear and Throat in the Cleveland College of Physicians and Surgeons Medical Department of the Ohio Wesleyan University Cleveland Ohio

Although a number of cases of dermoid tumors of the cornea have been reported from time to time it has seemed to me that a brief report of the only two cases that have come under my observation might be of sufficient interest to claim your attention

Case 1 —July 1880, Mr M G , aged 24, a peculiar growth from the cornea of left eye, protruding between the lids, present since birth, pedunculated, occupying the entire palpebral opening, measuring about one inch in length by one half inch in breath, and rather thickly studded with stiff black hair Being pressed together by the eyelids, the tumor presented upon superficial inspection the appearance of a small hair brush instead of an eye The eyeball was entirely concealed by the growth, but by opening the lids widely and pushing it downward some clear cornea could be seen, and fingers counted Patient declined operation at that time but returned in 1884 He thought the tumor was growing larger but it seemed to me about the same size as when first seen An anesthetic was given and the tumor removed without difficulty It was found to be attached to a little more than half of the cornea at its lower and outer portion, but peeled off smoothly, leaving a transparent cornea beneath

It extended close up to the sclero corneal margin but did not encroach much, if any, upon the conjunctiva, with which it seemed to be intimately connected The portion of the cornea occupied by the tumor became somewhat cloudy for a few days but soon cleared up excepting a small line running in a semicircle across the cornea, marking the point of attachment, vision fairly good , is able to read ordinary book print

Case 2 —July 15, 1893, Miss A P , aged 17, three small flat dermoid tumors of cornea of left eye Two of them were on the outer sclero corneal margin and each about one third the diameter of the cornea , the other a small one consisting of a fine line extending perpendicularly across the pupillary area almost at the center of the cornea The three tumors were all separated by clear cornea They had the appearance of ordinary integument with a slightly pinkish tinge Present since birth and no increase in size Patient was seen by Dr C R Agnew in 1877 It seems to me that I have seen a report of the case by Dr Agnew, but I have been unable to find it in the literature at my command Under a general anesthetic I dissected off the tumors Was very glad I gave a general anesthetic at the urgent solicitation of the patient because of the free hemorrhage which would have embarrassed me very much with cocain alone The case made an uneventful recovery, but with much more opacity of the cornea than I had hoped, judging from my experience with the other case There was a high degree of hypermetropic astigmatism and with full correction vision was only brought up to 20 200 S

Ryba[1] in 1853 collected twenty-seven cases that had been reported up to that time in human eyes, three in oxen's and four in dogs' eyes Mr Dixon reported a case of dermoid tumor the size of a hazel nut upon the lower part of the cornea and sclerotic of a little girl The tumor was removed and found to be white smooth and hard The cornea after removal was transparent but in three or four days became white and opaque

Cases have been reported by Graefe,[3] Virchow,[4] Arlt, Taleferro,[6] Hulke,[7] Wells,[8] Labrum,[9] Cooper,[10] Strawbridge,[11] Risley,[12] Roberts,[13] Fuchs,[14] Brose,[15] and others

Ammon[16] reports a case of coloboma of eyelids in which a dermoid tumor of the cornea filled the gap

Mr Swanzy[17] gives detail of a case he observed under the care of Von Graefe The tumor was very large and was removed by Graefe It occupied the whole of the depth of the cornea The anterior chamber was opened and considerable vitreous escaped

Milvalsky[18] (Prague) reports two cases of dermoid tumors of the eyeball The paper is published in Cezechesh with a résumé in French The author has reviewed the literature on the subject very carefully and has found recorded seventy-five cases of dermoid tumors of the eye-ball Seven of these he calls atypical, being connected with the eyelids Five of the cases were entirely corneal, and twelve were situated on the sclerotic and fifty-one were placed partly on the sclerotic

"The relation of these tumors to the conjunctiva varied In some the conjunctiva seemed to be replaced by the tumor tissue in others it [illegible] surface of the latter, while in most instances a portion of the growth was apparently covered by conjunctiva, while the remainder exhibited on the surface a pavement epithelium, papilla, hair follicles and fine hair The cystic form or closed dermoid is never met with in the eye "

A review of the preceding cases seem to show that they are all congenital, a few may be located on the cornea alone, a few on the sclerotic but the largest number involved both structures and are found most frequently at the outer and lower sclero corneal margin

Van Dusyse's[19] ingenious theory as to the origin of these tumors is not generally accepted, namely that the amnion was at one time united and through constriction and separation, there remained at the original point of contact amniotic cells from which later the dermoid cysts developed " A more reasonable explanation is the one generally accepted as to the etiology of dermoid growths in other parts of the body, *i e* an inversion of the epiblast during embryonic existence, an islet deposit of cells, which makes skin, sebaceous glands and hair follicle

Little need be said as to treatment Removal for cosmetic purposes is usually desirable Notwithstanding Von Graefe's unfortunate experience the danger of penetrating the eyeball is slight It does not seem to me that cauterizing the wound as recommended by most writers is necessary, and may only add to the amount of opacity present upon recovery The same objection is true with regard to the advisability of covering the surface of cornea exposed with conjunctiva, recommended by some writers

DISCUSSION

Dr Adelaide E Portman, Washington—From the situation it can be readily understood why it is so serious in removal as it involves the whole depth of the cornea and the sclerotic, removal causing results to visual acuteness Hirschberg reports a case, in a girl of 17, of enormous size in which the result was vision of normal acuteness

Dr J A White, Richmond—I reported a case of dermoid growth of the cornea in a man some years ago The growth was so large as to prevent closure of the lids, the cornea being entirely covered and the sight in consequence abolished It had begun at the corneal margin some ten years previously and gradually overspread the cornea in which by pressure it had produced ulceration, followed by cicatricial adhesions over one third of its surface Its removal was followed by favorable healing, the cornea cleared and subsequently the eyesight became nearly normal [illegible] as not [illegible] but was shown by the micr[illegible]

[illegible] S [illegible] open [illegible] rarity of dermoid growths of the cornea Any growth of this kind which invades the sclerotica must make any attempt at complete removal fatal to vision by the inevitable cyclitis which ensues A comparatively large growth located entirely in the cornea may be safely removed In the case of a man who lost the fellow eye, I removed a large dermoid tumor of the cornea, closing the wound by the Lembert suture, with the result of restoring such useful vision as enabled the man to go about alone If the sutures penetrate the whole thickness of the cornea the openings through which the sutures pass will continuously drain away the aqueous humor, keeping the sutures so long in contact with the surface of the iris as to lead to its fatal inflammation

WATER

BY I N LOVE, M D

ST LOUIS, MO

In searching for the striking and unusual we often overlook that which is trite and commonplace to our detriment Nowhere is this more true than in the practice of medicine I believe that we are, safe not only as teachers in medicine but among ourselves, in laying stress upon the importance of using the simplest possible means for gaining a given end The neophyte is not the only one who seeks for the unusual, for the formidable, as a means to an end and overlooks that which is near his hand Indeed all of us are prone to err in the same direction As a profession we need to call a halt, ever and anon to get down off of our stepladder in our search for the unattainable, to come down to terra firma and use the things that nature has given us Drugs, drugs, drugs, seem to be the chief inspiration in the life work of too many medical men, and in these modern days we must have a care in our use of animal therapy, for we know not as yet but what this form of medicine is quite as dangerous, if not more so, than the articles belonging to the mineral and vegetable kingdom, the drugs of which Oliver Wendell Holmes very truly said, "That the world at large would be better if they were all thrown into the sea," but the fishes would more than likely cease to be, as a result of the dumping

Water, which is everywhere near at hand, ready for use, is one of the most important remedial measures we can bring into play The hydropaths, who for long were looked upon as fanatics, have done humanity and the medical profession a service, in that they have demonstrated the great value of water However, the fanatic in the use of one remedy oftentimes is in danger of denying his patient remedies of value that would work in harmony with his special hobby Surely, when we recall the fact that more than 75 per cent of the whole make-up of the human body (including every tissue of the same) is water, we can appreciate its importance It has been demonstrated, time out of mind, that while water fulfills many other subsidiary offices, it is essential for the occurrence of molecular change, or mobility—the essence of the manifestations of life In the absence of water a state of molecular rest (which means the absence of activity) prevails

It goes without saying, that water in some shape or other, is one of the essential conditions of life and just as essential as solid matter, it not only entering into a constitution of every part of the body, but is required for various purposes in the performance of the operations of life Without it there could be no circulation or mobility of any kind ' It forms the liquid element of the secretions through the medium of dissolving and enabling the digested food to pass into the system and the effete products to pass out, a constant ingress and egress are occuring, and the former requires to stand in proper adjustment to the latter The demands for water are effected by the amount of muscular exercise and the degree of temperature to which the individual is exposed, as in both conditions the loss through the skin as well as through the lungs is greatly increased " It has been a popular impression for long that the drinking of water with the meals interferes with digestion in diluting the gastric juice, and as a result of this notion, the public have largely refrained from drinking water with their meals Pavey well says that it is a mistaken notion to think that when we drink with a meal we are diluting the gastric juice The act of secretion is excited by the arrival of the meal into the stomach, and the gastric juice is not there at the time of ingestion It happens indeed that the absorption of fluid takes place with great activity and the liquid drunk during the meal (unless the quantity be very great) becoming absorbed may be looked upon as proving advantageous by afterward contributing to yield the gastric juice which is required

For an irritable stomach or an attack of so-called bilious colic, nothing is superior to liberal quantities of hot water as pure as possible The first amount administered may be rejected, but if so, it accomplishes the washing out of the stomach If the drinking be persisted in, a large quantity will be retained and finally a relaxation of the pyloric orifice of the stomach will occur, and the water will pass freely into the smaller bowel, relaxing and stimulating secretion as it goes The intense pain of these attacks can often be promptly relieved and if helped by the addition of hot water applied over the stomach and bowels, through the medium of cloths saturated with the same, and occasionally sprinkled with small quantities of turpentine, which acts as a counter irritant In the majority of cases the stereotyped administration of morphin by injection, is uncalled for Indeed we are safe in saying that in the bulk of the attacks of acute indigestion and intense pain resulting therefrom, we had better relieve the condition in the simple manner suggested, rather than apply remedies which deaden pain, check secretion and retard convalescence, and frequently mask the preliminary symptoms of a dangerous disease Nothing will more promptly relieve a patient's suffering from the after-effects of a banquet or midnight dinner, where the victim has possibly tarried with and looked too long upon the wine which is red (and white wine too for that matter) resulting in the dark brown taste and that terribly different feeling in the morning, than the imbibition of large quantities of hot water The instruction to drink one or two pints of extremely hot pure water, prior to rising and sandwiching in between the various glasses a cup of black coffee, without cream or sugar, will give us a good result The hot water washes out the stomach from above downward, stimulates the activity of the excretory glands, soothes and tranquilizes the nervous system, which is thoroughly on edge, and the black coffee administered in the manner suggested, meets the necessities of the hungering and the exhausted nerve centers, serves as a disinfectant for the alimentary

---

Read at the meeting of the Mississippi Valley Medical Association St Paul, Minn, Sept 16 1896 canal and encourages diuresis The injuction to abstain from food for several hours will as a rule make our patient all right and in good shape for a hearty mid-day meal

While it is true that water does not in itself undergo any chemic alteration and hence is not susceptible of liberating force, does not in other words, constitute a force-producing agent, yet it contributes to chemic change by supplying a necessary condition for its occurrence in other bodies In other words the proper metabolism of tissues, the entire scheme of nutrition, depends upon water Not only do we need water then for the proper accomplishment of nutrition and as an element of food, but we need it for eliminating purposes Pavey has stated that it may be reckoned that we receive from about fifteen to twenty-five ounces of fluid into the system mixed with solid food that is consumed and, besides this, it is advisable that about sixty to seventy ounces and even in some cases as much more should be taken The average amount of urine passed daily may be said to be fifty ounces and there is considerable loss of fluid through the skin and lungs To meet this waste by elimination, compensation must be affected by a corresponding amount of liquid, as long as the fluid taken is devoid of noxious properties a free supply must be regarded as beneficial, forming as it does, a means of carrying off impurities from the system Pavey further says he believes that the benefit derivable from a course of water treatment is often in a great measure due to this cause Water then, taken in free quantities acts as a purifier of the system, flushing as it were the *animated system* of sewerage, dissolving out poisonous materials and waste products of the body, which otherwise might be accumulated For instance it is well known that uric acid, a very important factor in gouty conditions, requires a large amount of water to render it sufficiently soluble to be carried out of the system For fully fifteen years I have been impressed with the thought that the majority of people, sick and well drink an insufficiency of water I would advise the establishment of the water drinking habit on the part of children from the beginning, through life And as each year passes, I have been more and more convinced of the correctness of this position It is the universal observation that thin people are scant water drinkers and a change of habit in this regard often results in an improvement quite manifest Then again we will observe that the fat and well-fed looking ones are uniformly liberal water drinkers We have then in this, evidence of the fact that a free supply of water improves nutrition Furthermore, the one who does not drink water, often has a dark, swarthy, so called bilious complexion, inactivity of secretion, manifested in the appearance of the face whereas the water drinker has a clear, healthy complexion, suggestive of the fact that secretion is active and that the poisons due to waste are not retained and stored up in the system We can not impress too forcibly upon the young and particularly the female devotees of society, that the greatest improver of the complexion which they can have, is the free use of water internally and externally Surely if the general conditions of those who are supposedly well are improved, it follows that those attacked by disease in any form, will be the better for the free use of water When medicine is administered, it should be accompanied or followed by as large a quantity of water as may be retained by the patient Prompt solution, absorption, action and elimination of the medicine will be the result

For years, in the management of my typhoid fever patients, as well as most other diseases, I have insisted upon the drinking of a liberal quantity of water, endorsing by my practice the course of Debove, who administers almost to the exclusion of all drugs in typhoid fever from four to eight ounces of cold water, every two or three hours when awake, to wash out the poisons from the system The free secretion which follows its use, comforts the patient in every way and undoubtedly serves as a reducer of temperature This internal use of water accompanied by its proper external application almost excludes medicine from the field, though it has been my custom for years not less than ten, to use infinitesimal doses of the mild chlorid, eucalyptol, menthol and oil of gaultheria, for a gentle stimulant to excretion and local antisepsis for the alimentary canal, preferring always to have the bowels gently open with a view to eliminating all poisonous matters rather than a constipated or tied-up condition of the alimentary canal, with a consequent retention of poisons In this connection permit me to say, as I have repeatedly said in debate, that the views and treatment of my friend, Dr Woodbridge of Ohio, are in no way new, nor are they original They are simply the application of the accepted antiseptic and gentle eliminating treatment of typhoid fever I will grant that the extravagant manner of his presentation of the subject has resulted in a more general dissemination of the advantages of this treatment, but this is more than offset by the absurd position taken by him in stating that under this treatment he allows a complete recklessness in the matter of food and exercise I know Dr Woodbridge is honest, but I know furthermore as well as I know anything, that he is mistaken in his conception of typhoid fever, and many of his cases reported as such, have never been made acquainted in the remotest way with Eberth's bacillus, the causative factor

It is well known that there is no solvent which will remove poisonous materials, such as uric acid (the exciting cause of gout) and many other poisons from the system, so readily and completely as absolutely pure water Indeed, the temperature-reducing and gland-stimulating affect of copious water drinking has been utilized for many years, and more recently by Meigs, Cantani, Dujardin-Beaumetz, Debove and Sahli

Cantani is a great believer in the reduction of temperature slowly but surely by the regular drinking of large quantities of water Indeed, he believes in the liberal introduction of it into the alimentary canal from both directions

Dujardin-Beaumetz, no better authority in the world, promotes diuresis, or elimination or washing out of the products of organic disintegration (or waste) in disease by copious drinking of water

Debove administers, almost to the exclusion of all drugs, in typhoid fever, six ounces of cold water every two hours to wash out the poisons from the system

Simon Baruch of New York one of the highest authorities upon hydrotherapy and value of water enjoined as a remedial agent endorses the use of water by those whose names have just been cited, and even goes further

Every authority will sustain the t t the purer the water, the more complete the elimination and more satisfactory the result in every way

Let it be remembered that to Dr James Curry of Liverpool belongs the credit of first using the cold water treatment in a systematic way in fevers He employed as a rule cold effusions frequently and occasionally cold baths His method was adopted by many physicians and soon came into extensive use both in England and on the Continent in the treatment of many febrile affections and especially in the management of typhus, typhoid and scarlet fever It gradually fell into neglect, like many other excellent therapeutic medicines, and was for a long time almost forgotten Dr Ernest Brand of Stettin revived the cold water treatment of fevers in 1868 and the method came rapidly into use in Germany, Austria and Switzerland This history of the application of cold water bears out the thought that in these modern times, that many measures which have their seeming origin in Germany are more readily accepted and popularized than if coming from other directions There are many objections that can be presented to the extreme application of cold baths, as was the rule with Brand, the modification of Ziemssen being much to be preferred Ziemssen recommended the introduction of the patient into water having a temperature of ninety-five degrees, then cold water to be gradually reduced to seventy-five degrees Fahrenheit, or even below This method is much less apt to produce shock, and the pleasantness of the procedure is such as to render it much more acceptable to the patient and attendants To secure the same reduction of temperature to the patient a longer time is necessary for the bath The placing of a sensitive or nervous patient into an ice cold bath skirts the border line of the brutal and is to be condemned, except in rare cases This method is certainly to be condemned in the fevers of children Sponging of the surfaces with cold or tepid water in which a little alcohol or aromatic vinegar has been placed is often very comforting and soothing to the patient It does not reduce the temperature to any very remarkable degree but has a cleansing effect on the skin and stimulates its activity, and is for that reason oftentimes a great advantage

I am convinced that experience in the application of water in the treatment of fevers will endorse many of the conclusions of Brand, Ziemssen, Hare, Vouveret, Winternitz, Dujardin-Beaumetz, Vogl, Peabody, Austin Flint, Simon Baruch, to the effect that it is not only valuable as a reducer of temperature but as a stimulant and a helper in the direction of elimination and a tranquilizer and securer of rest and an aider in the digestive and assimilative processes essential to repair He who had ever seen a patient almost unmanageable with the delirium of high fever or the convulsions of childhood dependent upon fever, promptly relieved by a cool bath followed by restful sleep, can not require further argument Indeed, I believe that no one in the profession would deny that the utility of water used judiciously in this way, has been absolutely proven

The hot bath as applied to children suddenly taken with convulsions is often misapplied When we recall the fact that convulsions are more frequently produced by high temperature than any other cause, we can readily see the objection to extremely hot water baths Before being used the temperature should always be reduced and if it be used, the bath should be comfortably warm and cold water gradually added However, the hot water bath in many conditions in childhood is of great service in the treatment of those who are sick, particularly in its cleansing effect upon the skin, rendering the excretory appendages of the skin more active It serves admirably as a tranquilizer, producing restful sleep when applied immediately before retiring, to victims who are sufferers from insomnia and restlessness

We all know the value of hot water when applied locally to inflammations Recalling the parboiled, shriveled, whitened look of the washwoman, whose hands remain in hot water long, we can readily understand that the hot water drives the blood from the inflamed tissues and gives great relief to the pain, as well as removing the trouble permanently Racking headaches can often be relieved magically, as any lover of the luxury of a graceful barber and a comfortable barber's chair can testify, by the application of towels rung out in boiling water and laid across the forehead, eyes and part of the head which seems to be most affected Apparent suffocation and complete stenosis accompanying diphtheria and acute laryngitis is often relieved very satisfactorily by a liberal application for a few hours of cloths wrung out of hot water to the external parts

Liberal poulticing with soft cloths saturated with almost boiling water are cleaner and in every way to be preferred to flaxseed, bread and milk poultices, and other filthy abominations

---

THE TREATMENT OF DIPHTHERIA

BY DOWLING BENJAMIN, M D

CAMDEN N J

To thread one's way through the enormous and conflicting mass of statistics that have been published in regard to the treatment of diphtheria by means of antitoxin, or serum therapy, is an undertaking to appall the stoutest heart

By patience and application we may observe a few facts, however, standing prominently and seemingly substantial enough to remain as useful monuments to guide us through the wilderness of uncertainties to some safe vantage ground

THE RESULTS IN PRIVATE PRACTICE

A study of the results of the antitoxin treatment in private practice presents much greater difficulties, for obvious reasons, than does the study of the same subject in institutional practice

Exactly what the results have been can not be ascertained, as it is not possible to obtain the personal and private statistics of each individual physician as to its results and his death rate, nor would it be wise, since such results might do injustice to thoroughly competent men If results are particularly good, however, occasionally an individual practitioner will publish such, which seems to be the only way we can obtain them

The limits of this paper would not permit the quoting of each of the publications by private practitioners, giving the results of their individual practice The introduction of a few, however, will be necessary In the present enormous amount of literature and reports on the subject, the results obtained by any one man in private practice can have but little effect on the question

One year ago, Dr Rosenthal of Philadelphia, in a paper read at the meeting of the Medical Society of the State of Pennsylvania, arrived at the following conclusions: "Antitoxin is a specific for diphtheria. In early cases, those seen one or two days after infection, no death rate should be recorded. In laryngeal diphtheria, the so-called membraneous croup, antitoxin is especially indicated. It should be used in every stage and at any date of the disease, no matter how late we see the case. Its influence can be proven, for cases of laryngeal diphtheria perish from suffocation long before any toxic symptoms can be manifested." For that reason he strongly urges the necessity of prompt intubation when indicated, even if before the injection of antitoxin.

Regarding the use of antitoxin, he says: "Do not delay or hesitate in this disease because the case is not so bad, or because it might get well without, but use it at once; the earlier it is used, the more certain its success."

This and similar sentiments from other sources, and the very logical character of the theory of antitoxin treatment, based as it was on laboratory experiences, necessarily made an impression upon thinking physicians, and Dr. Rosenthal was not alone in this radical and sweeping position. It represented pretty fairly the sentiments of the writers on antitoxin during the winter of 1894-5.

Three days ago I wrote to a leading antitoxin firm to send me the latest data in favor of antitoxin, as I wished to use it in a paper.

This recent literature received consisted of a reprint from the *Atlantic Medical Weekly* for March 21, 1896. In this paper Dr. Rosenthal says, in speaking of the number of cases treated with antitoxin: "I have treated seventy-eight cases of diphtheria with but two deaths."

It is important to state, however, that Dr. Rosenthal has found that mercury is equally as good a specific for diphtheria as antitoxin, according to the *Medical and Surgical Reporter* of June 13, 1896, for at the Philadelphia County Society's stated meeting May 27, 1896: "Dr. Rosenthal said that *before* the advent of the antitoxin he had *always* considered mercury a *specific* for diphtheria. As early as 1885 he had given calomel in diphtheria but in rather larger doses than had Dr. Flick."

In laryngeal diphtheria he has given as high as five grains every hour—in fact, he has given as high as 120 grains to a child five years old, in twenty-four hours, nor did he notice that the child showed any of the physiologic action of the calomel. He was led to believe that to ptyalise a child who suffered from diphtheria was an impossibility, and he not only gave such large doses of calomel to these children, but he has used at the same time corrosive sublimate in enormous quantities, having introduced 1-500 solutions into the child's nostrils, and swabbing out the fauces with it, probably introducing into the body of the child about a grain of corrosive sublimate, inside of twenty-four hours.

If the doctor had deaths occur under the above treatment I believe he would have said so, as it was a vital point at the time, just as important as to state the death rate under antitoxin, and if he has treated seventy-two cases since the advent of antitoxin, he must have treated a great many more before, with as good or better results, or we will have to leave his evidence out altogether.

Dr. S. S. Haldeman, of Portsmouth, Ohio, in a paper read before the Ohio Medical Society, on May 28, 1896, says:

"I have had an experience of eight months in the treatment of diphtheria with antitoxin, embracing the administration of the remedy to seventy cases of the disease, several of them bacteriologically examined, and all presenting the usual well marked signs and symptoms of the disease, and occurring during an epidemic of a severe type, characterized by a high rate of mortality where the antitoxin was not employed in the treatment, without losing a case treated."

He used it for the purpose of immunizing in twenty-seven cases that had been exposed to the disease, with the desired result of preventing it in all but three cases. In these, the disease began before the end of the third day after immunization.

He also stated: "That in a child five years old he had used the antitoxin for the prevention of the disease, the child being perfectly well. The child died in four minutes. Other children injected at the same time were not injured by the antitoxin." He says: "As to the cause of the fatal result, it is not clear to my mind." He said further: "The wide adoption of antitoxin as a remedy in diphtheria enables one to draw some useful conclusions as to its value. Yet I speak with some caution and reserve, with my limited experience of the remedy, and the results in my own practice have led me to wonder if it were really the treatment with antitoxin, or the non-employment of remedies, such as chlorate of potassium internally, and the local irritants to the diseased parts, that had something to do with the uniform and rapid recovery of my cases."

"Usually in conjunction with the injection of antitoxin, I would give calomel freely, and a prescription combining a few drops of tincture of ferric chlorid in glycerin and syrup, to be given hourly." "After exfoliation of the membrane and the subsidence of fever, I would give small doses of quinin and strychnia every four hours, to a child one year old, and order this continued for not less than three or four weeks. Of the various local applications administered, I think most of that of Professor Loeffler. For a young child I have diluted the solution with alcohol and water, and directed that the mouth be swabbed out with this preparation, but in the case of older children and adults would advise the use of the solution in full strength. The preparation consists of menthol, 2½ drams dissolved in 9 drams of toluol, one dram liq. ferri chlorid, and alcohol, 2 ounces."

He used local disinfectants to prevent or limit the growth of bacteria in the throat and supporting treatment. He had but one case with laryngo-stenosis.

Query: Which one or two of the above remedies cured the disease?

It is well to remember that Professor Loeffler cured seventy-one consecutive cases of genuine diphtheria in 1894 with the same remedies that Dr. Haldeman used (except the antitoxin), during an epidemic, the general mortality of which was 25 per cent. (See Loeffler's report at the 8th International Congress of Hygiene and Demogrophy held at Budapest, Sept. 1894.)

THE USE OF ANTITOXIN IN GENERAL PRACTICE IN CAMDEN.

Since the introduction of antitoxin, July 5, 1894 (it is claimed by Dr. Robinson) it has not been very extensively used in Camden. As far as [illegible] can [illegible] number of cases in which [illegible] you exceed one hundred, and by quite a number of physicians

Last May Dr McAllister reported, in private practice, ten cases with two deaths, or 20 per cent, and at West Jersey Orphanage, nineteen cases with no deaths

Dr O W Bramer has had thirty cases of diphtheria treated with tincture chlorid of iron internally, and local antiseptic sprays of creolin without a death He tried antitoxin in three cases, no worse than some of the others, with one death, a mortality of 33 per cent

One means of ascertaining the results of the new treatment outside of hospitals, that we can use at present, is to take the general returns of the disease from all sources of private practice, ascertain the mortality and compare with an equal number of cases returned by private practitioners, not using antitoxin, and ascertain the death rate In this method, however, there are two sources of error One is the difficulty in knowing to what extent the antitoxin has been in general use, and in ascertaining whether the two sets of cases were in all respects sufficiently similar as to the prevailing type of the disease and their environment All the official returns available, however, are composed of both private and institutional practice, no attempt being made by the boards of health to keep separate lists

The results of treatment in 10,240 cases of diphtheria in the German hospitals and in private practice were recently reported to the Society for Internal Medicine by Professor Ulenburg Of this number 5,790 were treated with the antitoxin serum, with 552 deaths, a mortality of 9 5 per cent for all ages, 4,450 were treated by other methods with 652 deaths, a mortality of 14 7 per cent

The German government is interested in the sale of antitoxin, and most of these statistics are prepared by government officials It should be noted that most all the literature on the subject is being furnished to the profession by manufacturers and importers of antitoxin and I am sorry to find they sometimes leave out unfavorable reports, as I have ample proof

It is worthy of note that foreign statistics, especially the institutional, are so different from ours in their results that there can hardly be any comparison For instance, the high mortality averaging from 50 to 75 per cent claimed by European hospitals to have been their rate previous to the antitoxin treatment, is something an American practitioner can not understand Either Europe must be a very unhealthy place, or the professional skill is not equal to the American Their standard text-books have never made such statements of mortality

The most decided and brilliant test of antitoxin, and the most favorable so far, seems to have been the one reported by Dr Otto Katz of results obtained in the Kaiser und Kaiserin Friedrich Kinder-Krankenhaus of Berlin with Schering's antitoxin, in a paper read before the Berlin Medical Society, June 27, 1894 From January 1, until March 14, 1894, the date when the new treatment was begun, there were in 86 cases, 38 deaths, a mortality of 41 8 per cent

From March 14 to June 20, 128 diphtheritic children were treated with antitoxin, with 17 deaths In every case Löffler bacillus was demonstrated by means of blood serum culture Now, if we add to this 13 per cent the six moribund cases that were received at the hospital at the same time, it would give us a mortality of 19 21 per cent, as against 41 8 The above are the celebrated "brutal figures" which converted Professor Virchow

The other treatment has remained the same that it was before the injection method was introduced Local applications, sprays and salves were used as before Tracheotomy or intubation was done for the same indications When the antitoxin ran out in July in this institution the mortality rose to its usual high average and fell again on the renewal of the antitoxin treatment, *but the average of deaths* per year in proportion to population *is no less* than it was before the advent of antitoxin, though the remedy is said to be in pretty general use in Berlin

To return to the United States In Boston, during the year 1895, antitoxin period, 588 deaths occurred, or 11 for every 10,000 inhabitants For fourteen years preceding the antitoxin treatment the average mortality per 10,000 of population was 9 In New York, antitoxin treatment 1894-95, 3,993, or 10 deaths for every 10,000 inhabitants During the fourteen years preceding the antitoxin treatment the deaths averaged each year 10 per every 10,000 inhabitants, which is about the same as it was after the introduction of antitoxin The same is true of Brooklyn There were 1,139 deaths from diphtheria in Brooklyn during 1895, or 10 for every 10,000 inhabitants In 1890, before the antitoxin treatment, there were 902 deaths which is 10 per every 10,000 inhabitants These statistics are from official returns of the health department

In Camden, N J (from official records)

Year	Cases	Died	Death rate Per cent	Rate per 10,000 inhabitants
1893	285	66	23	16 60
1894	314	61	16	10 10
1895	168	29	18	4 50 (antitoxin)
1896, to June 15	117	20	18	6 40

HOSPITALS

In the Boston, New York and Philadelphia Municipal Hospitals, antitoxin has been applied thoroughly for a year It would be fair to presume that more light cases were sent to the hospitals since the advent of antitoxin than before, as physicians have improved greatly in the last two years in their habit of sending to the health officers notice of their cases They more fully appreciate the importance of the matter, and health authorities have more vigorously enforced the ordinances The returns have improved in Camden since the board of health proceeded against several physicians, and such is the case in all the large and progressive cities

In Berlin, after two doctors were arrested and punished the returns doubled For a generation the law has been, that all deaths must be returned before burial, but for various well known reasons many cases were not reported, unless likely to die or malignant

BOSTON CITY HOSPITAL

Year	Cases	Deaths	Per cent	
1892	387	185	47 80	
1893	419	203	48 44	
1894	598	266	44 48	
1895	1,566	207	13 21	(antitoxin)

WILLARD PARKER HOSPITAL, NEW YORK

1888	258	60	23 25
1889	383	79	20 62
1890	292	67	22 94
1891	289	85	29 41
1892	295	79	26 77
1893	343	108	31 41

Year	Cases	Deaths	Per cent	
1894	699	205	29 32	(antitoxin thoroughly used)
1895	778	190	24 42	"
1896 to May 1	251	58	23 10	"

The death rate at the Willard Parker Hospital was lower in 1889 and 1890 without antitoxin than it was under the antitoxin treatment carefully applied for over a year

I have visited New York for the purpose of investigating the subject I find Dr Winters of the Willard Parker Hospital has carefully investigated and verifies these statements His impression is that 38 per cent mortality would fairly represent the actual mortality of Willard Parker Hospital at the present time under serum therapy, if patients who have clinic evidence of diphtheria were subjected to this treatment to the exclusion and elimination of those cases which have no clinic data to warrant the diagnosis of diphtheria This was the percentage found by Dr Ewing in such cases in that hospital In laryngeal cases the mortality is 70 per cent in this hospital, while in Geneva it is 49 without antitoxin In the University College Hospital, London, it was 47 per cent without antitoxin In Philadelphia Municipal it is 52 per cent

I have anxiously awaited the criticisms by Dr J W Brannen of the Willard Parker Hospital in regard to the statements and figures given by Dr Joseph P Winters (already quoted by me) before the New York Academy of Medicine May 21, 1896 and I expected that he would be able to show many important defects in Dr Winter's statistics, but I really find that while he deprecates the unfortunate position in which Dr Winter places the hospital and discusses some of the subordinate issues and even goes so far as Japan for testimony, that he makes no perceptible impression whatever upon the elaborate paper of Dr Winters, whose figures seem like the Rock of Gibraltar to stand firm and unscathed after the assault The plain fact remains that the antitoxin treatment has not lowered the death rate, at least in that institution Nor was *early* treatment by antitoxin better than *early* treatment by other antiseptic practice

MUNICIPAL HOSPITAL, PHILADELPHIA

Results for 1895 were as follows Treated with antitoxin 302, deaths 85, rate 28 14 per cent , treated without antitoxin 404, deaths 105, rate 25 99 per cent , of the 302 antitoxin cases 51 were intubated, with 27 deaths, 52 94 per cent , of the 404 non-antitoxin cases 71 were intubated, with 40 deaths, 56 33 per cent , in favor of antitoxin 3 39 per cent , of the antitoxin cases 16 88 per cent were intubated, of the non-antitoxin cases 17 57 per cent were intubated, in nearly all the cases peroxid of hydrogen was used as a spray locally, in the 404 non-antitoxin cases tinct ferri chlor and hyd bichlor were used internally in the 302 antitoxin cases tinct ferri chlor was used The death rate was therefore higher with antitoxin

LONDON HOSPITALS

In the Northwestern and Southwestern Hospitals 1892, 1893, 1894, cases 4,672, deaths 1,187, per cent 25 4, in all the hospitals, 1895 (antitoxin) cases 2,182, deaths, 615, per cent 28 1

What is embodied in the foregoing in regard to antitoxin as a therapeutic agent must arouse in thinking minds a number of reflections No subject since the earliest dawn of medical science has been so thoroughly and extensively investigated in so short a time as has the use of antitoxin in diphtheria This is gratifying, for it shows that the science of medicine has emerged from its puerile stage and is advancing to maturity and accuracy By the enthusiastic and universal application of this method by the profession throughout the world we can settle in one year a question that would have taken 100 years by the slow progress of a few generations ago Electric transmission of intelligence and statistics have shortened periods of investigation at least 99 per cent

The results of treatment without antitoxin in the United States seems to be better than in Europe The results with antitoxin in this country have not been nearly so favorable as have those reported from Europe The fact is, is that nearly all the instances where antitoxin has been used it has not been relied upon exclusively, but other treatments of the most important and powerful character have been used at the same time

It is worthy of remark that in all cases where good results have been obtained, antiseptics or disinfectants have been applied to the throat and mucous membrane With all the mass of accumulated facts, experiences and figures, we will have to wait another year before the question of the value of antitoxin can be fairly and conclusively settled

To discuss the value of antitoxin as an immunizer would require an amount of space, statistics and time which would make this paper too long Suffice it to say on this subject, from what I can gather from a fair and impartial investigation of the subject it appears that antitoxin does immunize in the majority of cases, but not longer than about thirty days

It does not destroy the bacilli of diphtheria at all They seem to remain in the throat the usual length of time, a constant source of danger to other persons, unless local antiseptics be used Antitoxin is not an antiseptic, you can cultivate the bacilli in it

A number of cases are on record where antitoxin has been injected as an immunizer, or to cure patients, and has caused their death These are not sufficiently numerous, however, to forbid its use, provided its claims as a curative agent can be established, as the deaths occasionally occurring from the use of ether are not a sufficient argument to lay it aside as an anesthetic, and there is good reason to believe that carbolic acid or some other foreign substance in the antitoxin has been the cause of these accidents Nor is there a decided difference in sequelæ

The theory of the antitoxin treatment appears to be perfect and the treatment seems satisfactory in the laboratory, I have always been a student of the microbe pathology and I still have high hopes of the success of antitoxin, but as Professor Virchow has stated, 'Every consideration and theory must give way to the mere brute force of figures ' and there does not appear to be quite enough figures as yet

We are no doubt so familiar with the early statistics which came from abroad, inducing the extensive trial of antitoxin in this country, statistics of a very favorable character, during *the latter part of 1894 and the* early part of 1895, that I have naturally not encumbered this paper with them, as after a year s trial, the latest results are the only figures of real interest and importance, and they do not seem so favorable as we would have wished for I do not wish to be classed as a partisan in this matter I am simply an earnest seeker after truth trying to find [illegible] remedy

I have great confidence in the results obtained at the Municipal Hospital in Philadelphia, owing to my personal knowledge of the carefulness of Dr Welch, the physician in charge I have been using the streptococcus antitoxin in cases that have been brought into the Cooper Hospital with puerperal septicemia but am not yet ready to report on the results

THE ANTISEPTIC TREATMENT OF DIPHTHERIA

Nothing could be of more practical value in the science of medicine than results obtained by a physician in general practice and ripe experience upon a common disease, after fifteen or twenty years of careful practice and close observation, I wish to lay before you a presentation of what I consider the antiseptic method of treatment as applied to diphtheria

In 1877 in my graduating thesis at the University of Pennsylvania (which received honorable mention from that institution) I wrote as follows

"The evidence that disease may be caused by germs, or at least in some instances, amounts to demonstration, and it should be recollected that low organisms split up their nutrient matter, or pabulum, into new compounds, which in many instances have a powerful effect upon the human system, and may disturb their functions as long as they are generated within it When we view the practice of medicine and surgery with reference to this subject, we find that all those meteorologic, all those hygienic conditions, all those medical and surgical appliances and means which are most antagonistic to the form, growth and development of living germs and low forms of life, have been the most effective in the treatment of ontagia, even before the laws of germ development nd their relation to disease were so well understood s at present, practically (owing to the accuracy of clinical observations) contagia were treated in many instances as if their true nature had been known

"Quarantines were established and disinfectants quite intelligently used, but now, guided by a better knowledge and understanding of the nature of zymotic disease we are able to lay down a foundation of broad principles upon which to erect the superstructure of a more perfect practice "

Since that time pathogenic germs or bacilli have been so universally admitted by the profession to be the cause of the zymotic diseases that it can no longer be a debatable point in pathology

You can not have diphtheria without the presence of this microbe Like all other vegetables, and especially the low forms of life, it is necessarily subject to variations in the character and amount of its poisoning products, for the bacillus after all is not the real poison which causes such disastrous consequences in the human system, but the ptomain which it produces

Various staphylococci and micrococci found in connection with this germ in diphtheritic cases no doubt produce some of the lesions found in the neighborhood of the diphtheritic points, especially the secondary affections

IMMUNITY

It is claimed by good authorities that an attack of diphtheria does immunize a patient My own experience is that I have never known two well-marked attacks of severe diphtheria in the same person I have seen two cases followed in a year or two by a lighter attack

The literature on the subject would cause me to think that some must have had a different experience

THE MEMBRANE

Formation of the membrane —The formation of the membrane is not well understood It appears to be an exudation of fibrin from the capillary blood vessels, under a high state of irritation and congestion, in the same manner as it is produced by any other irritation or congestion, and may be seen sometimes thinner and sometimes thicker in stumps that are left open to "glaze," in peritonitis, croup, etc Now the question arises, as to the nature of those peculiarly malignant cases of diphtheria that show intense intoxication, and even die before any visible membrane is formed It seems quite probable that large surfaces of the pharynx and nasal cavity have been covered by the bacillus in very active and virulent form before the false membranes are seen, so that sufficient toxin has been absorbed into a susceptible system to produce fatal symptoms before the exudation has had time to form

Pseudo-membranous croup —I believe this to be an entirely different and distinct disease, clinically and etiologically While the Löffler bacillus is always found at some stage of true diphtheria, it is not found in croup, except as a rare and accidental visitor The microscopic and clinical pictures of these two diseases are totally distinct Croup usually begins at the larynx, little or no fever, usually progressive and fatal, simply by a mechanical stenosis of the larynx, occasionally extending into the bronchi, seldom visible in the pharynx, and without the Löffler bacillus Diphtheria on the other hand, usually begins with fever, symptoms of intoxication and one of the first things seen on examination is the exuded patch in the throat, often tinged a little yellow No doubt many cases of true diphtheria were formerly treated as cases of croup, or have been returned as such after death I do not believe that croup is a contagious disease Never but once in nineteen years have I seen two or three children with croup at the same time in one family

At present I am inclined to believe that membranous croup is not due to any bacillus, but to severe local congestion or a disturbed circulation, caused by exposure of parts of the body to cold and dampness

Follicular tonsillitis is sometimes mistaken for diphtheria, it differs clinically and microscopically, and I think we are rapidly approaching a period when it will be demanded of the entire profession to make use of the microscope in differentiating these closely allied throat diseases, and I believe that the Board of Health has done a good thing in ordering all cases of supposed croup to be reported to the Board in less than twenty-four hours

LOCAL QUARANTINE IN DIPHTHERIA

My experience has been that it is easy to quarantine a case of diphtheria in a room where there is a large family and many children, successfully preventing extension of the disease to the other inmates, as I do not think that the germs spread more than a few feet in the air at a time, but may be rapidly disseminated by contact or fomites But, in two instances where I had successfully quarantined a case in the house from the rest of the family, in about a year afterward a number of the family were taken with the disease, not having been exposed elsewhere, so that we were driven to the conclusion that quilts or something that was in the room during the previous sickness had not been properly sterilized, and the germs had been animated after this long period

This leads me to a very important reflection in regard to quarantine in a city, namely, if the case of diphtheria in a house was properly quarantined, why could not the family be permitted to go to their work, pursue their usual avocation, and not be submitted to the objectionable fate of being compelled to remain in that house during the disease, and, since the disease is more likely to be carried, after the general quarantine has been removed from the house, by the inmates for months or years, is it not equally safe with proper room quarantine to allow the inmates egress and ingress during the existence of the case in the house?

Since the authorities do not thoroughly and persistently quarantine a house usually during all epidemics, the inmates of the house go out and the neighbors intermingle, it might be more practicable and agreeable to a community for a board of health to quarantine a portion of the house This procedure has many things in its favor

How is the bread winner to pay his rent, when he has a family? How can he pay the doctor?

Under proper conditions he could see his child's face at evening if he is anxious to do so without carrying the disease

Intubation vs tracheotomy—I have performed both intubation and tracheotomy in a number of cases (I always prefer intubation) and I have had recoveries take place with intubation under conditions which I believe would have proven fatal had tracheotomy been performed however, we have tracheotomy to fall back on in case intubation fails

LOCAL TREATMENT

The symptoms are usually not very pronounced before the diphtheritic "patches" are visible I make the bacteriologic or culture test in all cases when possible From the foregoing statements it may be seen that I hold that this disease is essentially local and external, for anything on the mucous membrane practically is not in the system, but the products of the bacillus being absorbed into the system as fast as produced, cause the general and constitutional symptoms

Basing our treatment upon the views above stated, I have for over 15 years held, that the rational procedure, in combating this disease was simply to destroy the bacilli where they are located on the mucous membrane of the throat or elsewhere, by the proper applications of antiseptics or germicides and secondly, meeting the poison in the blood by such therapeutic means as physiologically and chemically were the best antidotes for it

Now, while many scientific and learned physicians have followed these lines in treating diphtheria, they have so frequently been disappointed in their results and struggled along with a high mortality (in many cases, 30 to 40 per cent), yet I have always contended that this is the correct line of treatment, and will give the best results if accurately and thoroughly carried out

The important consideration, therefore, is what local and general medication to use and equally important, the method of applying and using these remedies, for I believe that the failure to cure by this practice will be due either to a want of proper applications of the treatment, or to the fact that it has been commenced too late in the disease

If you will refresh your knowledge of anatomy by examining the drawings of the interior of the nose pharynx and larynx you will conclude that no treatment applied by the ordinary swab or probang, could

by any possibility reach the disease at its most dangerous points, and consequently must be very inefficient in nasal and laryngeal cases Even the physician could not apply the treatment thoroughly in an adult, and the idea of applying it in a struggling child is preposterous Moreover, since the treatment has to be applied every hour at least, it must be left to the family to be carried out It is therefore utterly impracticable, and I have found where it has been tried it did not accomplish the results There would be a considerable mortality

Antiseptics applied by the nasal douche, after Thudicum's method, do reach the nasal cavity thoroughly, but it is so difficult to accomplish that it can not be employed with children in private practice to any great extent, even if the physician superintends its use

Gargles are of little or no use in the nasal and laryngeal cases

The spray or atomizer therefore remains the only feasible method of applying antiseptics to all parts of the affected mucous membrane To the recognition of this fact, and its early and thorough adoption together with an efficient and pleasant antiseptic remedy to be used in the atomizer I must attribute largely my success in the treatment of this disease

I acknowledge that it is with the profoundest diffidence and respect for the criticisms of my medical brethren that I advance the following statement

For over ten years, including 100 cases, I have not had a death from diphtheria, unless a case that died about twelve years ago be included, connected with this were three other physicians and I have never been convinced that it was not a case of membranous croup A white membrane was very distinct in the larynx, extending downward I early practiced the antiseptic treatment and would not be justified in experimenting with other things, unless my results change, but I never use the bichlorid of mercury, nor do I think it should be used in this disease, because its action though beneficial is almost wholly due to its local effect upon the bacilli in the throat Many cases, especially in young children, have been injured by the too free use of this substance Other antiseptics, such as carbolic acid, salicylic acid, sesquichlorid of iron, are equally efficacious and may be used in ample quantity without the same amount of danger to the person

Since we usually depend on the laity any treatment that can be properly and thoroughly applied, even to young children, must have vast advantages over any other In severe cases I have all the mucous membrane thoroughly sprayed through the nose and mouth at intervals of fifteen or twenty minutes, or even longer, about fifteen seconds at a time, the child breathing as naturally as possible during the application The spray comes in contact with every part The membranes and symptoms rapidly disappear On several occasions I have suspended local treatment after their disappearance, and in twenty four or forty-eight hours the membrane would again spread over the throat, a few bacilli having been left alive, disappearing again promptly on resuming the local treatment, thus demonstrating its efficacy It is necessary to see that the atomizer works properly and that the attendant applies it thoroughly

Professor Loeffler claims that the disease being entirely due to germs lying in the throat, consequently in a position where they could be reached by local antiseptics, could be readily cured by local application, and instances seventy-one cases of diphtheria treated exclusively by local antiseptic applications, without a single death, in his private practice This statement was entirely consonant with my experience and practice, instituted ten years before his great discovery of the germ

If it be true (and I do not think that it can be successfully disputed now, that diphtheria is due to the presence of germs in the pharynx), why would not germicides destroy them? For we know that we possess a number of antiseptic or germicidal medicines that are invariably fatal to germs and can be used in quantities sufficient for that purpose without any detriment to the patient Holding the view of the disease that I have advanced, I could never understand why a local treatment would not be all that was required

Proffessor Loeffler, after various experiments, suggested a combination of

Menthol cryst	10 gm.
Toluol q s ad fac	36 c c
Alcohol absolute	60 c c
Liquor ferri sesquichloridi	4 c c

I have found the the formula of Professor Loeffler to be disagreeable to the patient, while the one I use has not that objection and is quite as efficient

Acid acet dilut	fl.ʒii
Pot chlorat	ʒss
Acid carbol	gtt i
Tinct ferri chloridi	gtt v
Pulv Alumen	gr v
Acid salicylic	gr i
Glycerin	fl ʒss
Aqua ros	fl.℥ss
Aqua q s ad	fl.℥iv

Misce Sig Use as directed

It is a clear, permanent liquid of a purple color

In making application to the throat of diphtheritic patients the doctor or nurse may use a disc of glass held between his face and the patient, to prevent infection from the sudden coughing and spitting of the patient

I always give tincture ferri chloridi in large and frequent doses, and I believe it produces favorable conditions of the blood, as it does in many other cases of septicemia, notably erysipelas, which often disappears under this treatment alone

One of the benefits derived from this remedy is its local action while being swallowed

Result under the local antiseptic treatment Benjamin, 100 cases, 100 recoveries, Loeffler, 71 cases, 71 recoveries

I will not weary you with a repetition of illustrative cases I hope the profession will give this treatment a fair trial and report on it

CASES IN POINT

I was called to attend a girl, 10 years old, whose brother, the only son, had died of the disease the day before The patient had diphtheria in a very grave form, pulse 140, temperature 104, respiration 40, and the throat covered with a thick membrane She was placed under treatment Marked improvement took place in twenty four hours At the next visit, the patch of membrane had diminished in size, the pulse was 120, the respiration 25 She was well in eight days, running about the house

In another part of the town I was called where five children had the disease, as well as mother and her baby, about six months old Three children across the street had just died and were awaiting burial Others in the neighborhood had the disease All these cases rapidly recovered I might go on until it would become monotonous, relating cases of which I have records My former assistant, Dr W I Kelchner, reports seventy-five consecutive cases by this treatment during the past three years, without a death

The more malignant the case the more brilliant the results that I have obtained by this treatment When I seek an explanation of this phenomenon it seemed quite natural that it should be so, for the abruptness and urgency of the onset of the disease causes the patient to send for medical assistance promptly, and the severe symptoms being due to the large number of germs spread over the mucous membrane of the pharynx and throat, the local antiseptic treatment is effective before sufficient time has elapsed to protect themselves by a false membrane

This was illustrated in the case of a woman who was taken with the most malignant symptoms, after having just buried her three children who died with the disease on that day She was practically well in forty-eight hours after treatment began, and attended to her household duties on the fifth day

If it be true that we can save our patients by local antiseptic treatment, properly applied early, the local treatment will displace the antitoxin treatment in general practice Patients can go about with less danger of spreading the disease when convalescing, since their throats are sterilized and no bacilli can be found by culture tests

Microscopic and culture tests should be made before using the treatment, as generally the bacilli disappears after using the antiseptic remedy

215 Cooper Street

THE STATISTIC EVIDENCES OF THE VALUE OF VACCINATION TO THE HUMAN RACE, PAST, PRESENT AND FUTURE

Read before the American Medical Association at the Jenner Centennial Celebration held at Atlanta, Ga May 1896

BY EUGENE FOSTER M D

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE AND STATE MEDICINE AND DEAN OF THE FACULTY OF THE MEDICAL DEPARTMENT UNIVERSITY OF GEORGIA AUGUSTA GA

(*Continued from page 811*)

PROPOSITION 7

In some communities and even nations a greater number of vaccinated and unvaccinated persons are attacked with small pox Anti vaccinationists parade such instances and use such data to bolster up their ridiculous assertions that such facts show the utter futility of vaccination Without a single exception every such effort is based upon the most shameful perversion of facts

Let us take Great Britain to illustrate this proposition It is true that in the epidemic of smallpox, 1871-72, a greater number of vaccinated died than those unvaccinated But does this fact prove the failure of vaccination ? By no means Why? The vaccinated portion of the population number thirty to forty times that of the unvaccinated In 1872 there were 300,000 of children under 5 years of age in Great Britain (Sir Lyon Playfair, *loc cit*) These were divisible into two classes, vaccinated and unvaccinated The vaccinated were thirty to forty times more numerous than the unvaccinated Now for results of vaccination In the vastly more numerous class—the vaccinated—the smallpox deaths numbered 1,780, while among the fractional portion of the population—the unvaccinated—the deaths number 413 According to Dr Playfair the mortality from smallpox was from 120 to 160 greater among the unvaccinated than the vaccinated The Registrar General of Great Britain showed that taking the whole community of the kingdom, there was only one death among the vaccinated for every forty among the unvaccinated

Let us take the epidemic of smallpox in London in 1882 During that year 2,317 deaths were registered from smallpox[3] (vide Registrar General's Annual Summary for 1882) Of these, 524 were stated to have been vaccinated and 962 unvaccinated, while regarding the condition of others as to vaccination, no statement was made It is tolerably certain that among the population of London not more than 10 per cent are unvaccinated, and if 10 per cent be supposed to be doubtfully vaccinated there will remain 80 (this estimate is certainly well within the true proportion) per cent presenting clear evidence of vaccination If, then the vaccinated and unvaccinated had been equally liable to fatal smallpox, the former would have died at the same rate as the latter, and since 962 of the unvaccinated died there would have died 7,696 among the vaccinated But the actual number of deaths among the vaccinated was 524, hence it is clear that the vaccinated and unvaccinated were not equally liable to death from smallpox

Moreover, if the mortality among children be considered the difference between vaccinated and the unvaccinated appears still more striking The deaths from smallpox during 1881 included 27 of vaccinated children under the age of 5 and 368 of unvaccinated children under that age If unvaccinated and vaccinated children would have died at the same rate as the unvaccinated, *i e* (taking the proportion of vaccinated and unvaccinated as previously stated) the deaths among the vaccinated children under 5 would have been 2,944 But the actual number was 27, and it is therefore obvious that unvaccinated children are liable to fatal smallpox to an enormously greater extent than vaccinated children , or, in other words, vaccinated children are to a larger extent protected from fatal smallpox

Dr Seaton, in Annual Report of the Local Government *Board of Great Britain, 1874, says on this subject*

But if the actual number of smallpox deaths in persons above puberty who had been vaccinated were equal to, or even exceeded that which occurred in persons who had not been vaccinated, *it must be borne in mind* that the proportion of our adult population which is protected against smallpox by vaccination is at least *from twenty five to thirty* times as great and much more probably from fifty to sixty times or more as great as that which is *unvaccinated* The relative number of persons who now a days attain manhood or womanhood without having been vaccinated is *very small* Examination of the young men who are recruited for the army has shown for many years past that, putting aside the small percentage who are marked with smallpox, the proportion of the remainder who do not present distinct marks of having undergone vaccination aver ages for the whole of England 3 9 per cent of those examined and for London separately, 2 8 per cent As these small proportions include all doubtful cases, it is clear then that somewhat considerably more than 96 per cent of those in England or than 97 per cent of those in London only must have been vaccinated Now recruits, I apprehend are not generally drawn from that class of the population which has been the most cared for , and there is, therefore, a reasonable probability that the proportion of the whole adult population of England which is thus protected against smallpox is much larger But even if the full proportion just given, or more than that proportion, be applied to the adult population generally—4 per cent being taken as unvaccinated and 96 per cent as vaccinated—it is clear that with equal actual mortality among the two classes, the relative mortality of the former would be twenty four times that of the latter The figures, then, are conclusive that vaccination as it was practiced in this country fifteen years ago and upward, instead of failing to protect persons from fatal smallpox after they had grown up has, in the immense majority of cases, very effectually protected them

But proof of Proposition 7 does not rest alone upon statistics as to the protective influence of vaccination in children Let us inquire as to the value of vaccination upon all classes and ages of population under recent so called failures to such extent as to have shaken the confidence of some few former advocates, and supplied vaccinophobists with what they term "an arsenal full of facts testifying to the utter futility of the measure " Let us take the most widespread and fatal epidemics of smallpox which have fastened their remorseless fangs into the bodies of communities since compulsory vaccination, and see if we can compare the results of vaccination and non vaccination This is the *only rational* test Ask vaccinophobists to select their own times and places of occurrence of smallpox *for this demonstration* and they will point to the epidemic of smallpox in Great Britain from 1870 to 1873 and with pride declare that in this epidemic we have an illustration of the futility of the prophylactic powers of vaccination We accept the issue thus made, and shall demonstrate the wonderful prophylactic power of vaccination in this time (their own selection), to the satisfaction of any sane or reasonable man Of this epidemic, Dr Seaton, who was specially detailed to investigate it, says "The epidemic of smallpox which began in England toward the close of 1870 and terminated in the second quarter of 1873, was part of a general outbreak of that disease, of world wide diffusion, marked wherever it occurred by an intensity and malignancy unequaled by any previous epidemic of the disease within living memory The outbreak seems to have begun in France about a year before it manifested itself in the United Kingdom In the last quarter of 1869 it was already making considerable progress in Paris Early in 1870 it prevailed in Orleans, Bordeaux, Lyons and other large towns, and in the course of the year extended with great mortality over nearly the whole of France Except, however, in so far as it was directly conveyed by the French prisoners to various places in Germany there was very little extension beyond France till toward the close of 1870 The epidemic then manifested itself in London, in two or three of the chief towns of Holland, in Milan, at Geneva and in some other places, becoming thereafter rapidly diffused over a great part of Europe During 1871, England and Scotland, Holland, Prussia and the whole north of Germany, Italy and Spain felt the full force of the epidemic, and the first beginnings of its ravages were experienced in some of the other countries of Europe, as in Ireland and Denmark In the course of this year it spread beyond Europe to various places in Africa (where it raged along the Gold Coast), to the West Indies and to North America During 1872, while still continuing its course in most of the countries it had attacked in 1871, it made further extensions over the continent of Europe, invading Austria, Hungary, Russia and Finland, over Africa and over North America, it spread, also, to South America and the South Sea Islands, and it invaded various places of the East In 1873 the greater part of its course in Europe had been run, but there were yet, during the earlier parts of the year, various countries and districts and important capitals, as St Petersburg and Vienna, still under its full influence By the middle of 1873, however, the pandemic extension of the disease in Europe may be considered to have terminated, and smallpox generally has since then been quiescent, though there have been some considerable local outbreaks"

---

[3] The Influence of Vaccination in the Prevention and Diminution of Mortality from Smallpox Presented to the Parliamentary Bill Committee of the *British Medical Association* By Dr Ernest Hart Chairman of Committee

Here, then, is, we hope, an epidemic of smallpox of wide spread prevalence and malignancy sufficient to satisfy these anti vaccinists Now for the lessons taught by this truly frightful epidemic, as applied to great Britain Seaton says "The varying intensity of different epidemics of the same disease is, indeed, a well known fact, and had been illustrated as regards smallpox, at various times, at the hospitals set apart for the treatment of that disease in London, the ordinary mortality of natural smallpox as therein observed, 35 per cent of the cases admitted having in certain epidemics been known to mount as high as 47 per cent, and that of post vaccinal smallpox to increase from 7 to 10 per cent But no experience which had been acquired in the hospital had led to the expectation that the ordinary rate of mortality to attacks would by any epidemic influence be nearly doubled Yet such was the case in 1871 and 1872, in the former of which years the deaths from the natural disease were 66 2 per cent and in the latter 77 per cent of the natural cases or in the two years combined (for the admissions in 1872 were too few to form by themselves a proper basis of comparison) 67 5 per cent of such cases This result is stated by Dr Munk and Mr Marson in their report for 1871, to have been due 'to the severity of the disease, and especially to the number of cases of malignant smallpox, the proportion of which to the other cases has been very largely in excess of anything within the experience of either of your medical officers'"

"In the hospitals of the Metropolitan Asylum district, in which the cases admitted would be of a more average character, the ratio of deaths to admissions was extraordinary, amounting to 44 80 per cent among the unvaccinated and 10 15 per cent of the vaccinated The ratio in the hospitals of provincial and foreign towns generally has ranged from 40 to 50 per cent among the unvaccinated and from 8 to 10 or 11 per cent of the vaccinated—enormous rates, and attributed everywhere to the same cause viz, the unusual proportion of malignant, black and hemorrhagic cases In several of these hospitals the rates were as high or higher than in the smallpox hospital of London as in the 'Barackem Lazareth auf dem Tempelhofer Felde,' at Berlin, which were used as additional smallpox hospitals during the epidemic in that city, and in which the mortality among the unvaccinated was 81 25 per cent and among the vaccinated 14 per cent, and in the hospital at Leipsic, in which the mortality among the unvaccinated was 71 *per cent* and among the vaccinated (including doubtful cases) between 9 and 10 per cent"

Let us now compare the mortality of this epidemic with that of other recent epidemics of the disease Here it is "In the thirty three years which at the time this *outbreak commenced* had elapsed, from the first establishment in England of a complete system of registration of the causes of death, there had been abundant illustrations of the varying fatality of smallpox epidemics, but it had been supposed by many—quite *erroneously as it now appears—that that period had been sufficient* to exhibit the limits of the fluctuations Only twice since the close of the great epidemics of 1837-41 had the smallpox deaths in England exceeded 7,000, viz, 1852, when they were 7,320, and in 1864, when they were 7,684 And though the epidemic of 1837-41, just referred to, had exhibited a mortality enormously in excess of these numbers (the deaths in 1838 alone having been 16,268), yet as this was anterior to any vaccination laws and at a time when the proportion of the population which was unprotected by vaccination was many times as great as it is now, a recurrence of any such considerable mortality as was then observed had been quite outside ordinary calculations The mortality of the 1870-73 epidemic has not indeed been by any means so great in proportion to population as was that of 1837-41, but it has approached it more nearly than had appeared possible During the 1837-41 epidemic there were registered from July 1, 1837, the termination of the epidemic in 1841, 48,012 smallpox deaths in a mean population of fifteen and one half millions, during the 1870-73 epidemic, 44,433 deaths in a mean population of nearly twenty-three millions The proportionate mortality therefore of the epidemic of 1870-73 has been less than two thirds that of 1837-41"

What of the mortality of smallpox in this epidemic of 1870 73 compared with the smallpox mortality of the last century? Dr Seaton says of it "The mortality of this epidemic was, as I have said, such as has not been known in England for thirty years, and has at least proved a complete answer, if, indeed, an answer had been required to the notion which had of late years been ventilated by some that smallpox was a disease naturally tending to extinction But, before proceeding further, it seems very important that it should be noted that the mortality of this epidemic, alarming as it has been, has not approached what was the usual annual smallpox mortality of the kingdom at the time when vaccination was unknown The annual average smallpox death rate of that period—not, be it observed, *the death rate of a particular year of special prevalence of the* disease, but the annual average death rate—was more than three fold the death rate of this, in our time, quite exceptional outbreak The estimated annual smallpox death rate of England in the last century was 3,000 per 1,000,000 of population the mean annual death rate of this epidemic was 928 per 1,00,000, having in 1871 been 1,024 and in 1872 833 per 1,000,000 The average annual smallpox death rate of the metropolis in the pre vaccin period was from 400 to 500 per 100,000 of population, the mean annual death rate of this epidemic was 148, having in 1871 been 243 and in 1872 54 And if an average be taken of the smallpox mortality of England for the whole twenty years (1854-73) during which there has been a compulsory vaccination law, a period which includes the whole of the recent epidemic, the annual death rate is found to be 245 per 1,000,000 of population, or less than a twelfth of the rate of last century"

And yet in the face of such facts as these Mr P A Taylor, M P of England, seriously asserts

"That the practice of vaccination affords no national protection from smallpox, and has had no effect whatever in preventing or diminishing smallpox epidemics That the mortality among vaccinated smallpox patients is as great as among unvaccinated"

I have no patience with a man who would seriously advance such ridiculous nonsense into the arena of scientific discussion I would as soon enter into debate with my horse as with such a man

Proposition 8

1 Vaccination performed in infancy in the best manner, confers upon the majority of these individuals absolute protection against smallpox during life

2 In not a few instances (the proportion being unknown) individuals properly vaccinated, at or or about the age of puberty partially or wholly regain that susceptibility to smallpox which vaccination had once extinguished in them

3 In the overwhelming majority of instances of individuals contracting smallpox after primary vaccination the disease is so mitigated as to be practically devoid of danger to health or life

4 The vast majority of cases of severe post vaccinal smallpox result from careless or inefficient smallpox

Inasmuch as in a considerable proportion of cases smallpox occurs a second time, and in rare instances, a third and even a fourth time in individuals, it is expecting too much of vaccination to demand that post vaccinal smallpox should not be found in a considerable portion of those who had been previously thoroughly well vaccinated

It must be confessed that the illustrious Jenner at first claimed that a successful vaccination afforded the individual absolute protection against smallpox In his work, "An Inquiry in the Causes and Effects of the Variolæ Vaccinæ," June, 1798, he says "But what renders the cowpox virus so extremely singular is that the person who has thus been affected is proven afterward secure from the infection of the smallpox"

Further experience caused Jenner to modify his views on this subject, as follows "Duly and efficiently performed vaccination will protect the constitution from subsequent attacks of smallpox as much as the disease itself will I never expected it would do more, and it will not, I believe, do less"[36]

It has long been demonstrated that the great benefactor of his race was mistaken even in his later estimate of the prophylactic powers of vaccination Primary vaccination is not and never was as fully protective against smallpox during life as a previous attack of smallpox As early as 1807 numerous cases of post-vaccinal smallpox were reported in England The Royal College of Physicians investigated the matter and found that some of the reported cases were well founded, but said "The number of alleged failures has been surprisingly small, so much so as to form certainly no reasonable objection to the general adoption of vaccination" Within the next few years the proportion of post vaccinal smallpox was found to be increasing, and in some epidemic seasons they presented a very alarming total[3] It was claimed that these cases of post vaccinal smallpox were not chargeable to vaccination properly performed, but were due to spurious vaccination But this claim was disproven to such an extent as to perplex and disappoint many advocates of vaccination Injudicious friends of vaccination endeavored to prevent publicity being given to the facts, and the enemies of the measure decried it with the zeal which has ever characterized their fight upon this, the most beneficent gift to man Simon very properly says "At no moment in the progress of Jenner's discovery had impartial investigation been needed more than now, for, partly by the facts themselves and partly by hostile overstatements of them, public confidence began to be disquieted There seemed a breach in the contract under which vaccination had been accepted In what had promised so much, failures were all the more conspicuous, men looked to them, even where most exceptional, rather than to the successes of vaccination, and there were (1820-35) not a few persons whose minds began to misgive them whether the old plan of smallpox inoculation had not perhaps been too easily abandoned"

In 1818, after vaccination had become general in Scotland an epidemic of smallpox visited the inhabitants—a large proportion of the smallpox patients having been previously vaccinated This gave rise to great surprise, and the prophylactic virtues of vaccination were freely discussed An examination into all the facts relative to these cases of post vaccinal smallpox so conclusively demonstrated the beneficial results of vaccination that public confidence in the measure was regained The cases of post vaccinal smallpox were so much milder than in the unmitigable variety that it gave rise to the term varioloid

In Sweden an epidemic of smallpox appeared in 1824, in which 103 cases of post vaccinal smallpox proved fatal, 69 of these presenting good vaccinal scars and 34 less perfect vaccin scars Smallpox assumed epidemic proportions also in Germany, France, Italy and London and in many cases appeared among the inhabitants who had been vaccinated in childhood

In Ceylon the government of Great Britain, at an early period of vaccination, had the population so generally vaccinated, and so successful did the measure seem that smallpox was wholly banished from the island for a term of years In 1819, however, Ceylon suffered a widespread epidemic of smallpox, which was marked by great virulence of the disease In this epidemic many inhabitants who had previously been vaccinated in childhood, contracted smallpox This island had a like experience in 1830, again in 1833 and again in 1836 In the epidemic of 1833 fully 75 per cent of those contracting smallpox had been vaccinated in childhood

Denmark was visited by several epidemics of smallpox between the years 1824 to 1835 Gregory says "Yet in no country in Europe has more attention been paid to the practice of vaccination, both as to the numbers submitted to the process and the purity of the lymph employed" Notwithstanding these facts in Copenhagen, between 1824 to 1835, 3,839 cases of smallpox were observed, 80 per cent of this number had been vaccinated during childhood Even under these discouraging facts the value of vaccination was conclusively demonstrated, for the mortality in post vaccinal smallpox was only 2 13 per cent

The British army furnishes valuable statistics proving the proposition under discussion From 1835 to 1838 the average strength of the army, including men, women and children was 105,000 This force (including women and children) had been thoroughly vaccinated, yet 1,025 of them contracted smallpox and 122 of them died, a mortality of 11 9 per cent

The records of almost all hospitals prove that the majority of cases of smallpox from a community generally vaccinated are among those who have been vaccinated during childhood Dr Gregory's service at the London Smallpox Hospital (1826 to 1850) has been divided into quinquennial periods with the following results In the first period the number of cases was 1,262, of which 34 per cent had been vaccinated, in the second period the number of cases was 1,331, of which 36 per cent had been vaccinated, in the third period there were 1,763 cases, of which 41 per cent had been vaccinated, in the fourth period, number of cases 1,643 of which 43 per cent had been vaccinated, in the fifth period, number of cases 1,780, of which 52 per cent had been vaccinated Thus we see a gradual though decided increase of cases in persons previously vaccinated—the proportion of cases of post vaccinal smallpox from the first quinquennial to the last having been 18 per cent

In the London Smallpox Hospital Marson says the total number of smallpox patients received during the ten years 1855 to 1865, amounts to 7,326, of which 78 per cent had been vaccinated

Dr Welch, physician in charge of the Municipal Hospital, Philadelphia, Pa, says that during the epidemic of smallpox, 1871-72, the number of cases received amounted to 2 377 of which 68 per cent had been vaccinated in childhood In the same hospital in the epidemic of 1880-82 the number of cases admitted into the hospital was 1,659, 54 per cent having previously been vaccinated

Similar data might be presented from numerous sources but it is unnecessary Enough has been given to conclusively prove that smallpox occurring in persons who had been vaccinated in infancy is of much more frequent occurrence than is witnessed in individuals previously attacked by smallpox

Let us now examine the question of redevelopment of susceptibility to smallpox This redevelopment of susceptibility progressively increases up to a given period of life, the greatest increase up to a definite point corresponding with the length of time intervening primary vaccination

The following tables, selected from many at hand, demonstrate this fact

Ages	Gregory of London		Helm of Württemberg	Mohl of Denmark
	Cases	Deaths	Cases	Cases
Under 5 years of age			40	11
From 5 to 10 years	5		68	102
From 10 to 15 years	25		186	17
From 15 to 20 years	90	6	275	187
From 20 to 25 years	106	16	239	[illegible]
From 25 to 30 years	55	8	172	19
From 30 to 35 years	13	1	75	2
Above 35 years of age	4			
Total	298	31	1,055	[illegible]

The following table compiled by Dr Welch from the Municipal Smallpox Hospital, Philadelphia, Pa, shows 2,907 cases of post vaccinal smallpox admitted into the hospital from 1871 to 1883, including the cases classified according to the quality of vaccinal scars in individuals below the age of puberty

		Cases	Deaths	Percentage of death
Under 5 years of age	Good cicatrix	1	0	
	Fair cicatrix	1	1	
	Poor cicatrix	[illegible]	1	
Total		10	[illegible]	
From 5 to 10 years	Good cicatrix	11		
	Fair cicatrix	9		
	Poor cicatrix	2	[illegible]	[illegible]
Total		4[illegible]	[illegible]	1[illegible]

---

[36] Seaton's Hand book of Vaccination p 223

[3] John Simon Royal Vac Commission 1889 p 78

		Cases	Deaths	Percentage of deaths
From 10 to 15 years	Good cicatrix	45	2	4.11
	Fair cicatrix	18	2	11.11
	Poor cicatrix	36	4	11.11
Total		99	8	8.02
From 15 to 20 years of age		388	47	12.11
From 20 to 25 years of age		745	96	12.88
From 25 to 30 years of age		580	92	15.86
From 30 to 35 years of age		356	64	17.97
From 35 to 40 years of age		249	51	20.48
From 40 to 45 years of age		161	35	21.67
From 45 to 50 years of age		105	22	20.95
Fifty years of age and upward		175	63	36.00
Grand total		2,907	191	16.80

Sufficient data have been presented to conclusively demonstrate that it is and has ever been during the practice of vaccination, fallacious to contend that primary vaccination always confers upon the recipient an immunity equal to that which he would enjoy had he previously had an attack of smallpox. From numerous data throughout this paper it must be evident to every student of vaccination that a primary vaccination made in infancy confers upon the individual so treated a positive and well nigh unvarying protection against smallpox for an unknown number of years, generally to puberty, and that in a considerable, though undetermined, proportion of such individuals a redevelopment of susceptibility to contract smallpox ensues in consequence of the deterioration of the protective power which vaccination had exerted against smallpox. This fact in no wise militates against the efficiency of vaccination in the prevention and control of smallpox, nor does it detract one iota from the splendor of the discovery of the immortal Jenner. An appreciation of this fact places vaccination upon the impregnable rock of truth, and enables Jenner's successors to intelligently take the one additional step necessary to stamp out smallpox, *i. e.*, revaccination.

It being an incontrovertible fact that a thorough primary vaccination protects the majority through life from smallpox, but that in a considerable proportion of primary vaccinations a redevelopment of susceptibility to smallpox ensues, and inasmuch as we are utterly unable, from examination of vaccin cicatrices or otherwise, to decide who are not enjoying the full protective influence of vaccination, it is our duty to revaccinate every vaccinated person within ten or fifteen years from the primary vaccination, and in the face of exposure to smallpox to revaccinate even though the primary vaccination had been performed only several months previously.

PROPOSITION 9

A good primary vaccination may be made in infancy, coupled with successful revaccination at puberty, as fully protects every individual so treated from smallpox as if he had previously had an attack of smallpox.

Revaccination at puberty being admitted to be necessary to confer upon the recipient the full protective benefit of vaccination, let us ascertain what this protective power has been ascertained to be.

Experience in Smallpox Hospitals. Dr. Welch, physician in charge of the Municipal Smallpox Hospital, Philadelphia, Pa., says: "My experience in hospital work, which as regards time, comprises a period of more than twelve years (Jan. 1, 1871 to May 1, 1883), entirely agrees with that of Marson and other observers just quoted. Only very few patients during that time have been admitted into the hospital under my charge, with varioloid, who presented evidence of having been successfully revaccinated, and these few had the disease in so mild a form that death has not occurred in a single instance. During my service no person entering the hospital in any official capacity, as resident physician, steward, matron, nurse, laundress, or other employe, who had taken the precaution to be revaccinated before entering upon duty, has suffered from smallpox in any form whatsoever. But, on the other hand, I have seen a few employes in whom revaccination was for some cause omitted, become infected by the disease."

Dr. Seaton (in report of Medical Officer of Privy Council and Local Government Board for 1874) says: 'The observations which were made during the recent epidemic (1870-1873) afforded remarkable evidence of the value of revaccination, not merely in controlling the mortality from smallpox, but usually preventing altogether the occurrence of the disease. Its power of preventing smallpox under circumstances the most favorable for contracting it was tested on a very large scale on the nurses, servants and attendants of the various hospitals established for the treatment of the epidemic in the metropolis and in the provinces, the attendants in the hospitals of the Metropolitan Asylum Districts alone amounting at one time to above three hundred. In every hospital report which has reached me it is specially stated that not a single one of these officials, who had been revaccinated before coming to take duty at the hospital, contracted smallpox. On the other hand, a few cases occurred among some nurses and servants in the hospitals of the Metropolitan Asylum District, whose revaccination in the pressure of the epidemic had been overlooked, and there was one case in a nurse who, having had smallpox previously, had consequently not been vaccinated on coming into the hospital. There was also a modified case in a nurse in whom revaccination had been performed, but not till after her arrival at the hospital, and when the smallpox infection had already been received. The cases of smallpox which were admitted for treatment in the several hospitals in persons who had been successfully revaccinated were very few and very slight. In the hospitals of the Metropolitan Asylum Board, in which upward of 14,800 cases of smallpox were treated, there were but four cases in which there was good evidence of revaccination having been performed with effect, and these were all light cases. In Liverpool, says Dr. French, revaccination was found a constant and perfect protection against smallpox. In the Newcastle-on-Tyne smallpox hospital, in which 778 cases were treated, there were two in which revaccination was alleged to have been successfully performed, one of them ten years and the other four years before the attack of smallpox, both of them recovered. In the same hospital eight patients were admitted, stated to have had smallpox, five of whom were distinctly marked by it, one of the three not marked died, the remaining seven all recovered. In the Leeds hospital there were four cases in which previous revaccination was alleged, but in none of them was the evidence of revaccination conclusive. One of them, in which the revaccination was said to have been done at seven years of age, was fatal; the other three cases were mild. There were three (fatal) cases of smallpox in persons believed to have had smallpox previously, but the evidence of the former smallpox is not stated. Similar infrequency and mildness of smallpox after revaccination was noted in the hospitals abroad. In the municipal smallpox hospital at Berlin, in which 1,529 cases were treated who had been vaccinated, only nineteen of these were in persons (all above 30 years old) who had been successfully revaccinated; they were all of them cases of varioloid, or of variolous fever without eruption, and none of them died. In the same hospital there were seven cases (three of them fatal) in persons who had previously had smallpox. In the Baracken Lazarethe, used also as smallpox hospitals in the same city, in which 1,805 cases were treated in persons who had been vaccinated, seven only were in persons who had been successfully revaccinated, of whom six had a mild attack and one (a woman 60-70 years old) had the hemorrhagic form and died. In the hospital at Leipsic, out of 1,501 vaccinated patients there were thirteen who had been successfully revaccinated in early life, all of whom recovered; in the same hospital there were twenty-two cases in persons who had had previous smallpox, and of these six died. In the hospital at Hamburg the cases in persons who had been revaccinated were more numerous, amounting to fifty-nine out of a total of 2,267 vaccinated patients, and there were three deaths."

Dr. Marson, having the greatest experience perhaps of all writers upon this subject, says of the test of vaccination in preventing smallpox: "For thirty years we have revaccinated all the nurses and servants who had not had smallpox, on their coming to live at the smallpox hospital, and not one of them has contracted smallpox during their stay here."

[38]*Manchester Royal Infirmary.*—Dr. Henry Thomkins, medical superintendent of the fever hospital belonging to the Manchester Royal Infirmary at Monsall, in a paper recently read at Owens College, said: "The most striking of all evidence is, perhaps, that derived from the smallpox hospitals themselves. Here the protective influence of vaccination is seen and proved in a manner beyond all cavil. At Highgate, during an experience of forty years, no nurse nor servant, having been revaccinated, has ever contracted smallpox, and evidence of the same character I can myself bring forward, for, during the whole time that I have had charge of the fever hospital more than a thousand cases of smallpox have passed under my care, yet no servant, nurse, porter, or other person engaged there has, after revaccination, ever taken it, though exposed daily to infection in its most concentrated form. . . . . Again, among all the students who during the past two years have attended the hospital for clinic instruction, not one has suffered, all having been revaccinated before being permitted to enter the smallpox wards. . . . . I defy the most enthusiastic or conscientious of anti-vaccinators to produce evidence like

---

[38] Annual Report of the Board of Health of Detroit, Mich., 1882, pages 109 and 110.

this on his side of the question, or to bring forward even half a dozen persons, choose them whence he may, who have not been protected against smallpox, and expose them as the students are exposed, without more or less of the number taking the disease."

At Versailles, in 1828, during an epidemic of smallpox of marked severity, revaccination was first tested as a means of checking the ravages of smallpox. A large number were revaccinated, and no one of these revaccinated individuals contracted smallpox.

In Copenhagen, there were three severe epidemics of smallpox between the years 1828 and 1835, during which not a single revaccinated person was attacked by smallpox.

In the epidemic in Heidelberg, 1843-44, notwithstanding vigorous and thorough vaccination, a large number vaccinated ten or more years previously contracted smallpox, yet not one revaccinated person was attacked.

In Wurttemberg with a vaccinated population of 1,263,298 during five years the total number of cases of smallpox was 1,677,—354 of these were cases of confluent smallpox, 1,043 were cases of varioloid—being about one case of failure of protection against smallpox to 217 vaccinated persons. In a few years subsequently, of 44,000 revaccinated subjects, 20,000 took the vaccin disease perfectly, 9,000 imperfectly, and failed with 15,000, the successful revaccinations being almost exclusively in those who had been vaccinated many years previously and only 3 of these in a subsequent epidemic of smallpox contracted the disease.

Of 14,334 revaccinations in the army of Wurttemberg, 1831–1835, 8,845 had what are described as genuine vaccin marks or scars, and of this number 31 per cent were successfully revaccinated, aborted vaccin vesicles in 29 per cent., and revaccination failed in 40 per cent. With those having imperfect marks of previous vaccination, revaccination succeeded in 28 per cent., modified in 26 per cent., failures 46 per cent. Mr. Simon, in his able digest of the subject, published by the General Board of Health, shows that, during the years from 1833 to 1837, notwithstanding the fact that smallpox had been sixteen times brought into the army of Württemberg, there had ensued among the 14,334 revaccinated soldiers one single instance of unmodified smallpox.

In the Prussian army, in 1840, revaccination was performed upon 43,522 soldiers. Upon these soldiers were found distinct vaccin cicatrices in 34,573, indistinct vaccin scars in 6,177, in 2,772 persons no scars of previous vaccination were found although they had formerly been vaccinated. The result showed 20,952 successful revaccinations, 8,820 partially successful, and 13,750 unsuccessful revaccinations. Revaccination was practiced in this army because of the increase of the number of cases of post vaccinal smallpox among the soldiers. For ten years prior to 1831 these cases had been observed, and from 1831 to 1833, 312 deaths had occurred among the troops formerly vaccinated. For twenty years subsequent to revaccination two deaths annually have occurred from smallpox, whereas 104 deaths annually occurred before revaccination was practiced.

In the Bavarian army revaccination has been compulsory since 1843, and for twelve years—1843 to 1855 as shown by the report of the minister of war—not a case of unmodified smallpox had occurred. A few cases of varioloid had occurred during this period of time, but not a single death from smallpox.

Dr. de Kerschensteiner chief medical officer of Bavaria, as the result of official statistics of Bavaria for ten years, 1871–80, says: "Of those once vaccinated, 12 per cent. of those attacked, of the revaccinated only 7½ per cent., but of the unvaccinated, 46½ per cent. died of smallpox."

The annual reports of the Medical Departments of the Army and the Navy of Great Britain, afford most striking proof the protective power of revaccination in adult populations. The soldiers and sailors serving in the United Kingdom may be looked on as virtually a wholly protected force, for now, for several years past, every man serving in the Army or Navy, whether or not he has marks of smallpox or of previous vaccination, is required to be vaccinated on entering the service. This rule has been in force in the army since 1858, but until some ten years later, there was no rule in the navy requiring the vaccination of all who entered, whether previously protected or not. This has, however, now been rectified and the result is seen in the fact that whereas in the days of the absence of such rule the smallpox death rate was much higher in the navy than in the army, the rate is now considerably lower, being in fact, for the six years 1873-78, absolutely *nil*. Indeed, in the whole of the British Navy in all parts of the world, numbering 46,400 men, there were in 1878 but nine cases of smallpox, four on the home station, three on the East India, one on the Mediterranean, one on the China stations. All these nine cases are noted as mild, and were unquestionably modified by revaccination. In the very large proportion of the men employed in both services, the protection against smallpox is that afforded by vaccination. In the year 1877 only 5.45 per cent., of recruits proved on examination to have marks of smallpox, while 90.85 had marks of vaccination, and 3.69 had neither vaccination nor smallpox marks.

If the records of these protected services be examined to see what ravages are now made in them by smallpox, the disease which, according to Sir Gilbert Blane, was, before the discovery of vaccination, "one of the great embarrassments to the operation of armies," and obliged ships of war occasionally to quit the seas, we find that during the eighteen years 1859-76 inclusive, the annual deaths from it were considerably less than one per 10,000 (.643 only) amongst troops serving in the United Kingdom. More than a third of the whole of the deaths during these eighteen years occurred during the smallpox epidemic of 1871-72, the exceptionally severe character of which has already been adverted to. Among the sailors employed on the home force, there were, during the 20 years, 1859-78, as nearly as possible, one per 10,000 (1.0085) attacked annually with smallpox. During the same period the cases of smallpox did not exceed annually 9.05 per 10,000 soldiers and 16.16 per 10,000 sailors. If the influence of the ferocious epidemic of 1871-72 be duly allowed for, a steady decrease in the number of cases and of deaths will be observed from the commencement. In fact, omitting these two years, there has not been a single death from smallpox in the navy 1864 and 1880 *i. e.*, sixteen years ago. The recent statistics of the army are hardly quite so favorable, but still they show the year 1865 to 1880, with the exception of the epidemic years 1871-72 only one single soldier out of the 80,000 troops serving in the United Kingdom, has on an average died of smallpox in each year.

TABLE O.—Table showing for each of the years 1870-83 the mortality from smallpox in Berlin, in London and in Vienna per 100,000 inhabitants.

Year	Berlin	London	Vienna	Year	Berlin	London	Vienna
1870	28.37	30.20	46.71	1877	0.40	70.98	81.01
1871	632.56	242.16	74.90	1878	0.78	38.81	7[illegible].11
1872	138.61	53.80	536.98	1879	0.75	12.13	40.91
1873	11.21	8.55	228.50	1880	0.81	12.59	73.[illegible]2
1874	2.47	1.66	135.26	1881	4.74	61.91	12[illegible].9[illegible]
1875	5.19	1.32	113.50	1882	0.43	11.07	108.29
1876	1.81	20.80	167.80	1883	0.33	3.00	9.60

Average for nine years from 1875 to 1883: Berlin, 1.7; London, 25.83; Vienna, 89.29.

The above table furnishes incontestable proof of the efficacy of revaccination. The vaccination law of Prussia requiring vaccination at the age of 1 year of age and revaccination at the age of 12 years was enacted April 8, 1874, and has been rigidly enforced. In England, primary vaccination is compulsory but revaccination, while urged upon the people, is not required except in the face of exposure to smallpox. In Austria neither vaccination nor revaccination is compulsory. The Austrian government warmly recommends vaccination and revaccination, but citizens adopt or reject the recommendation at will. Now, for the result. For the five years in the table, 1870 to 1874 inclusive, prior to compulsory vaccination, the average annual smallpox mortality per 100,000 inhabitants of Berlin was 162.64, while during the nine years of enforcement of compulsory revaccination at 12 years of age, it was 1.7 per 100,000 inhabitants. In London, it was 66.27, while during the nine years 1875 to 1883 inclusive, it was 25.83. In Vienna, 1870 to 1874 inclusive, it was 205.41, while in 1875 to 1883 inclusive it was 89.25.

Again, during the nine years, 1875 to 1883 the average annual smallpox mortality in each of the three cities was as follows: Berlin, 1.7; London, 25.83; Vienna, 89.29 per 100,000 inhabitants. What is lacking to convince any sane man when such figures are presented?

In the smallpox epidemic in Sheffield, England, 1887-88, as previously shown, a house to house examination made under direction of Dr. Barry, inspector of the local government board, disclosed the fact that 64,431 citizens of Sheffield had been revaccinated and only 27 or 0.04 per cent. of the total revaccinated population had contracted smallpox, and one person, rather more than 0.001 per cent., died. 8,198 of these revaccinations were made prior to 1887, and of this number 25 or 0.30 per cent. contracted smallpox and 1 or 0.01 per cent. died. The remaining 56,233 were stated to have been revaccinated during 1887-88, and of these 2 persons or 0.004 per cent. were said to have contracted smallpox and none of them died. The facts detailed by Dr. Barry show however [illegible] ther these two cases were smallpox.

The enumerators under Dr. Barry repo

number of persons living in Sheffield who had suffered attacks of smallpox prior to 1887 amounted to 18,292 persons Of these, 23, or 0 13 per cent, contracted smallpox, of which 5, or 0 3 per cent, died, the percentage of deaths to cases of second attacks of smallpox having been 23 5 per cent

VACCINATION AND SMALLPOX IN UNITED STATES ARMY AND NAVY

The following tabular statements relative to vaccination and smallpox in the United States army and in the United States navy have been kindly furnished me by Surgeon General Sternberg of the army and Surgeon General Tryon of the navy These tables richly illustrate the value of vaccination in prevention of smallpox

In the army all men are required to be protected from smallpox by vaccination at time of enlistment Now, for the result For the eight years, 1884 to 1891 inclusive, in an army never numbering less than 23,226 men, there were 17 cases of smallpox and only three deaths from this disease

In the navy for the sixteen years, 1880 to 1895 inclusive, among 68,944 men there were 95 cases of smallpox and only five deaths therefrom

Vaccination and Smallpox United States Army, Years 1884-91 inclusive

Years	Mean Strength	Cases Vaccinated	Cases Vaccination Undetermined	Primary Vaccination	Revaccinations	Total	Primary Successful	Revaccinations Successful	Total Successful
1884	21 034			819	6 839	7,658	271	856	1 127
1885	21 138			1,370	7,175	8,815	878	1,110	1,488

SOCIETY PROCEEDINGS

American Association of Obstetricians and Gynecologists

Ninth Annual Meeting held in Richmond, Va, Sept 22-24, 1896

(*Concluded from page 816*)

Dr WILLIAM G MYERS, of Fort Wayne, Ind, read a paper entitled

ATRESIA WITH RETENTION OF THE MENSES, TREATMENT

The author reported two cases of atresia, one with absence of the vagina and uterus and the other with retained menstrual *fluid* The last was operated upon successfully He believes that in a case of atresia of the vagina with retention of menstrual fluid in the uterus, an operation ought to be completed at one sitting, adopting the direct method He thinks the teaching in a recent work that "the best way is to make a small opening into the mass and allow the contents to flow away gradually," is not sound He could not therefore see in rapid evacuation such great dangers as were referred to in the books

PRINCIPLES AND PROGRESS OF GYNECOLOGY

The president's address was delivered by Dr JOSEPH PRICE, of Philadelphia He first thanked the Association for the distinguished honor in electing him president, which he said was the most gratifying expression of personal and professional kindness He said the Association was made up of earnest, enthusiastic and eminent men of the medical profession We had more than a passing interest in the record of the transactions of our medical and surgical associations From them the history of the progress of medical and surgical science would be made up, they would reflect the advanced thought and opinions, the strength of the endeavors, the results of clinic experience and research of the profession of this period We had the inspiration of the reflection that our high service was that of humanity, and Dr Price said the members were there to learn through the interchange of the best counsel how to make that service the best

Dr GEORGE H ROHÉ, of Catonsville, Md, read a paper on "Some Causes of Insanity in Women," of which the following is an abstract

The general causes of insanity are the same in women as in men, but there are modifying conditions in the life history of men and women that influence the causation of mental disturbances in the two sexes General paresis and alcoholic insanity are more frequent in men because the latter are exposed to their causes to a greater degree and intensity Menstrual, puerperal and climacteric insanity are on the other hand self evidently limited to women

Women are especially subject to mental disturbances dependent upon their sexual nature at three different periods of life puberty, the child bearing period, and the menopause The functions and activities peculiar to these periods have an intimate etiologic relation to certain insanities It is probable, however, that these functions have no influence in the production of insanity in their normal condition It is only when the functions are disturbed, or when pathologic conditions are present that they have any unfavorable influence upon the psychic functions

At the period of puberty, menstrual derangements are not infrequently causative of mental disturbances which do not yield until the menstruation becomes normal In the puerperium, insanity is dependent upon septic absorption, or the consequences of other morbid conditions of the reproductive organs Lactational insanity may be due to physical exhaustion, but in some cases pathologic conditions of the genitals or of the breasts seem to have an etiologic relation At the menopause the disturbances of nutrition associated with the arrest of menstruation often produce insanity, and in many of these cases there will also be found abnormal alterations of the reproductive organs The insanities following gynecologic operations are either due to septic conditions, or are merely due to the rapidly induced menopause Their frequency has been much exaggerated

Dr WALTER P MANTON, of Detroit, Mich, read a paper on

THE RELATION OF VISCERAL DISORDERS TO THE DELUSIONS OF THE INSANE

He said, that the delusions of the insane are often an expression of somatic peripheral irritation has long been recognized, but observation leads Dr Manton to believe that the importance of these mental manifestations as indices of bodily suffering was frequently ignored as a mere phase of the brain disorder, especially in the instances of supposed fancied visceral disturbances

For convenience of consideration, he placed the so called visceral lesions in four classes 1, Delusions arising de *novo from* the diseased activity of the brain, 2 delusions regarding external or visible abnormal bodily conditions, 3, delusions arising from easily determined visceral disorders, and 4, delusions dependent upon obscure abdominal and pelvic states The last three classes were briefly considered

One can readily understand how visible bodily defects may be misinterpreted and the mind of the patient become confused as to the real nature of the condition which is always more or less open to inspection The site of a dermoid tumor *slowly* developing in the abdominal walls led one of his patients to believe herself pregnant, but the removal of the growth soon dispelled the illusion In another instance a uterine fibroid called out the same impression, and the patient requested the physician to listen to "hear the young ones" The appearance of a complete procidentia uteri in another case gave rise to the idea that the protruding mass was the male organ, and under such conditions the patient could no longer retain her feminine appellation, and immediately rechristened herself "John" Such examples might be multiplied, for they were of frequent observation by all who had to do with the insane In such instances the connection between the delusion and the somatic disorder was obvious, being, as it were, on the surface In the third class, however, the relation of the condition to the expressed idea was not always so apparent

The author reported interesting cases In each of the patients the delusions referred chiefly to the abdomen, and in each an abnormal condition of some of the viscera was found but a condition in which the early intervention of surgery would have afforded great, if not permanent, relief to the sufferings of patients Laparotomy, in properly selected cases of the insane in whom visceral delusions are a pronounced and constant feature of the mental disorder, was not only justifiable, in his opinion, but urgently demanded in the interest of the patient

Dr **David T Gilliam**, of Columbus, Ohio, read a paper on

OOPHORECTOMY FOR THE INSANITY AND EPILEPSY OF THE FEMALE, A PLEA FOR ITS MORE GENERAL ADOPTION

The author showed in this paper that oophorectomy was a logical and legitimate operation for the epilepsy and insanity of the female Insanity is hereditary, as also epilepsy They constitute the greatest curse to humanity An insane father or an insane mother brings more misery into the world than any other father or mother The offspring of such a parent, when ushered into the world, would be confronted by the awful specter of impending doom, and though he called on the rocks or mountains to fall on him, the curse would pursue and overtake him Dr Gilliam then gave a picture from real life He would limit the operation to those in whom the malady appears in some way to be connected with, or dependent on sexual disturbance He would go further and include all who were willing to undergo the operation to save themselves and their offspring from the miseries which awaited them

Dr **J F Baldwin**, of Columbus, Ohio, followed with a paper entitled

TREATMENT OF THE STUMP TO PREVENT ADHESIONS

He estimated that about 1 per cent of all cases operated upon die from intestinal obstruction, the result of adhesions to the stump To diminish as much as possible the danger of adhesions, he recommended the careful closing in of stumps by a peritoneal flap, and described the method of securing this flap In cases where the pedicle is, after a simple ovariotomy, not too large, he recommended that the pedicle be so ligated that the ends of the ligature were on the anterior face of the pedicle, that the ends of the ligature be then carried across the face of the stump, down and through the broad ligament, transfixing the ligament from behind forward The ligatures should be passed through about half an inch apart As the ends are drawn through and tightened, the raw end of the stump is rolled down and under the broad ligament, so as to be entirely protected He had used this method in a large number of cases and with entirely satisfactory results

Thomas E McArdle of Washington, D C, read a paper entitled

ABDOMINAL SECTION FOR TUBERCULAR DISEASE

The author formulated in a terse manner what had already been done by surgical means for the relief of women suffering from tuberculosis of the generative organs There is no doubt that tubercular disease of the female genitalia is more frequent than is generally supposed Every portion of the genital tract may be affected, the order of frequency for the various portions being the tubes, body of the uterus, ovaries vagina, cervix and vulva The tubes are affected in all cases, the body of the uterus in about three fourths of the cases and the ovaries in about one half of all cases Tuberculosis of the body of the uterus is not at all a rare affection and has been frequently discovered in autopsies upon phthisical subjects It can be the only focus of disease of the body, but it is generally associated with disease of the tubes and is generally secondary to disease of that organ Of all the female genitalia, the vulva is the least liable to tubercular infection The author then dwelt upon the etiology of tuberculosis of the female genitalia, after which he detailed the various ways by which the disease might be caused or transmitted

The treatment of tuberculosis of the vulva, vagina and cervix did not come within the scope of the paper The destruction of the tuberculous focus by fluid or solid caustics had been advocated by some surgeons, and if these means were not satisfactory, extirpation of the part was recommended We had a very efficient means for the removal of the tubercular ulcers of the vagina and vulva in the application of the tincture of iodin They rapidly disappear under its use In case of failure, however, excision could be practiced When the cervix is involved, and not the body of the uterus, the method of treatment advised for the vulva and vagina should be given a fair trial, but if they prove ineffectual no time should be lost in amputating the cervix When the endometrium is involved there is a diversity of opinion as to the best method of procedure It has been recommended to first curette the organ and remove all evidence of disease The iodoform suppositories are introduced into the uterus If there should be a recurrence of the trouble, removal of the organ is advised If we bear in mind that tuberculosis of the body of the uterus is so frequently associated with the same disease in the tubes and ovaries, it seems to Dr McArdle that having once ascertained the existence of tubercular disease in the uterus, it is our duty to look for a similar condition in the tubes and ovaries, and, if found, it behooves us to waste no time in curetting the uterus and treating it with iodoform, but to proceed at once to the performance of an abdominal section for the removal of the uterus, tubes and ovaries This heroic method of treatment is advocated in primary disease of these organs In a case complicated with tubercular peritonitis there would be no special danger in removing the tubes and ovaries We all know how many cases of that disease have been cured by section and drainage We could then curette and treat the body of the uterus

Dr **Charles A Reed** *of Cincinnati, Ohio, read a paper* entitled

MELANO SARCOMA OF THE FEMALE URETHRA, URETHRECTOMY RECOVERY

This interesting case was as follows Mary E Y, aged 64, single, was brought to his private hospital Dec 3, 1895 The patient had had no previous serious illness There was no history of tuberculosis or syphilis in the family The vaginal condition of the genitalia precluded the supposition of venereal infection of any character Her general health was good, although there was some emaciation about the neck and breasts, the latter of which were flabby—changes no doubt incident to age Careful examination revealed no diseased conditions about either the lungs or heart Careful palpation and percussion of the abdomen yielded negative results

About eight months previously, *i e*, in April, 1895, she began to notice some pain accompanied with blood on micturition This was shortly followed by a more or less constant pinkish discharge from the genital fissure The self examination which followed revealed a tumor at the meatus urethræ This tumor continued to increase in both size and hemorrhagic tendency until she was prompted to consult Dr Morris, who curetted the neoplasm thoroughly and treated it with styptics When the patient came under Dr Reed's care he found a black lobulated and eroded mass about three centimeters in diameter separating the labia majora The orifice of the urethra was in the very center of this mass A careful vaginal examination was not made at the time, as the vaginal structures, present in their integrity, rendered such an operation very painful

Operation was done the next day, December 1 The small blade of a Jones' speculum was introduced, the patient being in the Simon's posture, the urethra was exposed in its entire length A longitudinal incision was made through the mucous membrane along the dorsum of the urethra from a point where the presenting part of the mass was eroded to the base of the bladder Another incision through the mucous membrane was made at right angles to the foregoing at point far enough above the eroded mass to insure healthy tissue The mucous membrane was then dissected back in two lateral flaps and the urethra was enucleated The urethra was found to be distinctly conical in shape, the base of the cone being at the meatus, the apex at the bladder Care was taken to dissect out the canal to a point manifestly above the zone of malignant involvement When this point was reached, but a slight distance from the bladder, the canal with the neoplastic walls was excised The cut margin of the cystic segment of the canal was seized at various points in its circumference by Kocher's forceps, brought down by gentle traction and fixed by interrupted sutures of silk worm gut to the vaginal mucous membrane A self retaining catheter was inserted and the patient put to bed The sutures were removed on the eighth day The catheter was dispensed with on the twelfth day The patient sat up on the fourteenth day when she found that she could retain her urine and void it at will She was dismissed December 21, entirely healed She remained in good health until July 1 following—seven months when she again summoned Dr Morris because of some stomach symptoms He found her suffering from persistent vomiting, and with a large mass in the epigastrium This mass rapidly increased in size until it occupied all of the area between the navel and the breast, its nodular characteristics becoming more and more pronounced She died of exhaustion July 14, 1896, having had no recurrence whatever of the urethral trouble No autopsy was permitted

Dr J B Murphy of Chicago, addressed the Association on

THE SUTURE OF LARGE VESSELS INJURED IN OPERATIONS

He demonstrated the method employed by him He said in 1762 Lembert conceived the idea of suturing injuries to vessels He made two experiments, in both of which he failed Dr Murphy then referred briefly to the experimental work of other surgeons along this line, pointing out their successes and failures His own researches and operative work lead him to believe that, where a large vessel is injured in an operation, a transverse division of it, not exceeding two thirds of its circumference, the surgeon can resort to immediate suture without resection, and, if the field of operation be aseptic, can feel more certain that he will have union of the vessel and continuation of the current than he could where he sutures the intestine as for resection of the bowel He believes from his observations that the changes are better with the suture The importance of this concerned surgeons more in the treatment of aneurysms

Coming to the question of stab and bullet wounds of the extremities, he said there was a great field for improvement in our past operative work Formerly, we ligated vessels, and when this was done the inevitable result was death of the limb He believes that now such limbs can be uniformly saved, particularly in the aseptic cases With his present method of suturing large vessels, he is not afraid to suture any vessel in the body, feeling confident that adhesion or union will take place

CONTUSIONS OF THE ABDOMEN

A paper on the subject with report of cases and conclusions was read by Dr W G Macdonald, Albany, N Y

Contusions of the abdomen are always grave injuries The question of surgical intervention, although much discussed, can not be regarded as satisfactorily settled Seven cases of traumatic rupture of the stomach and small intestines are reported Two operations were undertaken, one recovery, one death the eighth day after operation from second rupture All the inoperative cases died Reference is made to the general absence of evidence of contusions in the abdominal walls when serious visceral injury has occurred Very slight causes, particularly if the intestinal canal is distended with fluids, may produce intestinal rupture, as the falling out of bed, a blow from a barrow handle The early symptoms of intestinal laceration are not always distinctive An analysis of two hundred cases of intestinal laceration as associated with abdominal contusion was made with a view to determining the symptoms The following topics are considered the important ones History of the nature of the injury, shock or collapse, pain, vomiting, pulse, temperature and physical signs That careful investigation of a given case will usually show sufficient symptoms to make an early exploratory abdominal section imperative

The following officers were elected

President Dr James F W Ross, Toronto, Ontario

First vice president Dr Geo Ben Johnston, Richmond, Va

Second vice president Dr John C Sexton, Rushville, Ind

Secretary Dr Wm Warren Potter, Buffalo, N Y

Treasurer Dr X O Werder, Pittsburg, Pa

Place of meeting Niagara Falls, N Y Time August 24, 25 and 26, 1897

The American Public Health Association

[Special Correspondence of the Journal]

The Twenty-fourth Annual Meeting of the American Public Health Association held at Buffalo, N Y, Sept 15-18, 1896

(Concluded from page 818)

Friday, Sept 18, 1896 Morning Session, 9 a m

The Association met an hour earlier than usual and listened to the final announcements of the local Committee of Arrangements by Dr Howe, for the excursions to follow the adjournment in the afternoon and next day

The Secretary reported that the Executive Committee had recommended the passage of the following resolutions which had been referred to it

1 The resolution of Dr Whitehall of New Jersey, that the standing committee on legislation be requested to report methods for rural sanitary administration which are in its judgment the most useful and promising

2 The resolution of Dr Walter Wyman of Washington D C

Whereas, yellow fever is believed to be the most subtle and dangerous of all epidemic diseases, and whereas, it is ordinarily conveyed into a new country from an infected seaport of another, and whereas, the continued and persistent presence of this disease in any seaport is believed to be unnecessary and may be prevented by proper engineering and other sanitary measures, therefore be it

Resolved, 1, That it is the duty of every government possessing seaports thus infected to institute such engineering and other sanitary measures as shall remove this menace to seaports of other nations, 2, that it is the duty of the governments continuously threatened with the invasion of yellow fever from a seaport in which this is allowed to persist, to make such expostulations to the government in possession of the offending seaport as shall cause the latter to adopt sanitary measures necessary to remove this obstruction to commercial intercourse and menace to human life

3 The resolution of Dr Durgin of Boston, protesting against the passage by the Congress of the United States of the proposed act preventing experimentation on animals

The Executive Committee further recommended the continuance of all the special committees except that on the centennial of vaccination, and the consolidation of the committee on the cause and prevention of diphtheria with that on the cause and prevention of infant mortality

Dr Wright of Connecticut inquired what had become of his resolution recommending the discontinuance of oyster planting at the mouths of polluted streams, and when informed that it had been tabled by the Executive Committee, for the reason that it considers the effort should be to first prevent the pollution of the streams, gave notice of an amendment to the constitution, making the Executive Committee consist of nine members, three of whom shall be elected annually

The Secretary reported forty additional names recommended by the Executive Committee for election to membership, for which the Secretary was instructed to cast the vote of the Association in block

Dr Probst, of the Auditing Committee, reported that the accounts of the Treasurer had been carefully audited and found correct

Mr Crosby Gray, Secretary of the Advisory Council, reported that the following members had been nominated by the Council as officers of the Association for the following year

For President, Dr Henry Buckingham Holbeck of Charleston, S C, Health Officer of the city of Charleston

For First Vice president, Dr Peter Henderson Bryce of Toronto, Canada, Secretary of the Provincial Board of Health of Ontario

For Second Vice president, Dr Ernest Wende of Buffalo, N Y, Health Commissioner of the city of Buffalo

For Treasurer, Dr Henry Dwight Holton of Brattleboro, Vt

For Members of the Executive Committee, Dr Henry Mitchell of Trenton, N J, Secretary of the State Board of Health of New Jersey, Dr U O B Wingate, Secretary of the State Board of Health of Wisconsin, and Dr Jésus E Monjarás of San Luis Potosi, Mexico, President of the Superior Council of Health of the State of San Luis Potosi, who were all thereupon elected to these respective offices by the vote of the Association

Ex presidents Gihon and Formento were delegated by the Chair to conduct the President elect to the platform, who made a very feeling address in acknowledgment

Mr Gray further reported that the Advisory Council had selected Toronto, Canada, as its place of meeting in 1897 Dr Plunkett, President of the State Board of Health of Tennessee, moved to substitute Nashville, Tenn, in which he was ably seconded by Dr A N Bell of Brooklyn, N Y Professor Bracken of the University of Minnesota moved to amend, being largely seconded, by substituting Minneapolis, Minn, and he was followed by Dr Benjamin Lee, Secretary of the State Board of Health of Pennsylvania, who presented invitations from the Mayor of Philadelphia, the board of health of that city and the State Board of Health to meet in Philadelphia which was ably seconded by Dr Gihon, who as a Philadelphian argued the propriety of holding the twenty fifth meeting of the Association—its quarter centennial—in that city, where it had not assembled since 1874 He said that the presence of the Mayor of Ottawa, the capital city of the Dominion, backed by a strong delegation bearing an urgent invitation to go to that city, in a measure obliged us to hold our next meeting in Canada at Ottawa, having already met in Toronto in

1886 and in Montreal in 1894 After a lengthy and lively debate by the advocates of the various cities, Philadelphia was selected as the place of meeting in 1897

The appointment of Dr **Domingo Orvañanos** of the City of Mexico to be Assistant Treasurer for Mexico was then announced, and members appointed on the special committees authorized by the Association

The members of the new committee on transmissibility of infections and periods of danger from infected persons, constituted in accordance with the recommendation of the President in his annual address are Professor Eduardo Liceaga of the City of Mexico, Dr John L Leal, of Paterson N J, Surgeon Fernando Lopez of the Mexican Army, Medical Director Newton L Bates, U S Navy and Surgeon General J J Kinyoun, U S M H S

Professor Stephen Smith of the City of New York was appointed Chairman of the new committee on international cooperation in preventing the transmission of contagious diseases with authority to select his associates

The President, Dr Liceaga, then extended an earnest invitation on the part of Dr Rafael Lavista, Dr Manuel Carmona y Valle and himself as the Committee of Management of the 2d Pan American Medical Congress to all the medical members of the Association and their professional friends to attend that Congress which opens in the City of Mexico, November 16 and continues until the 19th

The thanks of the Association were then tendered the retiring President, who eloquently responded, expressing the hope that the community of interest between the United States and Mexico shown by his election might be unending, and to the retiring First Vice President for the able, prompt, and energetic manner in which he had assisted the President during the protracted sessions, and after a graceful response on his part, the scientific work was resumed in the following order Report of committee on the "Relation of Forestry to Public Health," by Professor **Robert C Kedzie**, of Michigan, Report of committee on "Transportation of Diseased Tissues by mail," by Dr **Henry Mitchell**, of New Jersey

Dr **Lee** commended the committee (Drs Mitchell of New Jersey, LaChapelle of Montreal and Orvananos of Mexico) for the admirable work they had already accomplished and in recognition of the fact that the Hon William L Wilson, Postmaster General of the United States had permitted the transmission of diseased tissues through the mail making their distribution possible, offered a resolution expressing the appreciation of the American Public Health Association of the deep scientific discernment exhibited by the Postmaster General in so doing

A paper "On Statistics of Vaccination and Mortality from Smallpox in the city of Mexico, 1872 1895," was read by Dr **Jose Ramirez**, who said that vaccination met with no opposition in Mexico, where it was compulsory, and consequently smallpox had become very rare, the epidemic outbreaks occasionally occurring being due to foreign importation A paper "On Drunkenness a Vice, it should be so treated," by Dr **A Nelson Bell** of Brooklyn, N Y This paper advocated the punishment of voluntary drunkenness as a misdemeanor, with increased penalties for repitition of the offense against society "Municipal Cattle and Meat Inspection, by Dr **Peter H Bryce** of Toronto, "The Prophylaxis of Scurvy in Prisons by Pulgue," by Dr **Francisco Martinez Baca**, of Puebla, Mexico Vice President **Woodhull**, in confirmation of the statement of Dr Baca, said that the use of the maguey juice had long been known to medical officers of the army serving in the Mexican frontier as an excellent remedy for scurvy

The following papers were presented "The Relation of Noises to Public Health," by Dr **William C Krauss** of Buffalo, N Y, "The Degeneration of the Human Animal Through the Nursery and Schools," by Dr **J B Learned** of Massachusetts, "The Importance of Supplies of Pure Water," by Dr **J L DeHart** of Brooklyn, N Y, "Racial Deterioration," by **Lawrence Irwell**, M A, of Buffalo, N Y, "The Protection of the Innocent from Gonorrhea," by Dr **Ferdinand C Valentine** of the city of New York "The Necessity of Isolating Beds in Hospitals by means of Windows between Them,' by Dr **Jesus E Monjaras** of San Luis Potosi, Mexico "Filth Deposits with Regard to Public Health," by Drs **Jose D Morales** and **R E de Guerrero** of Mexico

The program having been concluded, Medical Director **Gihon**, United States Navy, rose to say that he had deferred to the last to make formal announcement of the recent death of two of the most distinguished members of the body, Dr **Joseph M Toner** of Washington D C, one of its founders in 1872 and its second President (1875), and Dr **Jerome Cochran** of Mobile, Ala, State Censor of Alabama and senior member of the Advisory Council who since 1878 had never failed in his attendance at the meetings when that was possible and who until a few weeks ago anticipated with great pleasure being with us at Buffalo, and offered a resolution of sorrow and regret, which was adopted by a rising vote After appropriate valedictory remarks, the President at 2 P M declared the twenty fourth meeting adjourned

An excursion around the harbor and an exhibition drill by the life saving service during the afternoon, and an excursion on the following day to Niagara Falls, by steamer on the Niagara River to Chippewa, by trolley along the Canadian bank to Brock's monument and Queenston Heights, by boat across the river to Lewiston, thence by trolley through the gorge to Niagara Falls, where dinner was served, and back to Buffalo by train closed one of the most interesting and successful meetings in the history of the Association

---

Second International Congress of Gynecology and Obstetrics

(Continued from page 761)

The discussion of pelvic suppurations showed that the conservative operators were in the majority Doloris (Paris) remarked that the fact which established with the most certainty the evolution of the subject under discussion was the return backward "We have been sliding down an incline at a dizzy rate, and we are now working our way back " This is indicated by the more general adoption of vaginal incision The success of this simple and familiar operation augurs the adoption of still simpler methods and promises to restore early uterine therapeutics to its true importance Anterior vaginal celiotomy is a more recent but valuable conservative process Since we find that pregnancy occurs sometimes even after double lesions, conservative processes have acquired a new importance The conservative tendency which has been manifested at the Congress is logical and bound to assert itself more and more After mentioning that the severest and most virulent processes rarely generate pus, and that about 40 per cent of pelvic suppurations contain a sterile fluid without pathogenic action, he described the unreliability of the symptoms upon which we have to base our diagnosis and concluded with the assertion that the treatment of pelvic suppurations is akin to the treatment of pelvic inflammations, and should follow the same general and absolute therapeutic rules, beginning with simple methods and proceeding to others as may be found necessary What we most need is better knowledge of the evolution of pelvic inflammations, especially of salpingo ovaritis, as this is the most frequent, the cases tending naturally to recovery with a series of recrudescences, gradually subsiding in intensity, and those in which the acute attacks extend beyond their usual term with complications that involve the general health, or when the lesion becomes permanent and some etiologic factor is discovered, tuberculosis, syphilis, arthritism, neuropathy, alcoholism, etc He asserted that no real information is to be derived from the statistics of radical operations performed without any preliminary conservative treatment, and emphasized that the only treatment for pelvic suppurations was to try the simplest means of cure first and only proceed to sacrificial measures as a last resort

Doederlein (Leipsic) considers that if there is pus in the tubes or ovaries total ablation of the diseased organs is the only chance of cure But the uterus and ovaries may be left in certain cases He prefers Pean's operation when the entire genitalia have to be removed, but when the pus has disappeared, anterior and posterior colpo celiotomy may be preferred, as this in some cases allows a radical operation

Segond (Paris) spoke in high terms of the American method, which allows the total ablation of the uterus and its adnexa with "veritably marvelous security,' as he ascertained for himself by watching the American surgeons at work He has also performed it himself recently, with success each time He called attention to the importance of liberating the cervix as a preliminary to vaginal hysterectomy, whether it is amputated later or not The cervix free, the broad ligaments can be sectioned at the base As these are the only obstacles to the descent of the uterus, the *fundus* can be seized at once Liberating the cervix also lessens the dangers of injuring the ureters

Henrotay (Antwerp) stated that gonorrhea is by far the principal cause of suppurated adnexa and that the majority of cases now called puerperal, are really due to gonorrheal infection Prophylactic treatment should be based on the extreme severity of gonorrheal affections in women and the obligation of physicians to fully inform every man with acute or chronic urethritis of this fact Medical treatment s [illegible] in every case where possible If an operatio [illegible] prefers the vaginal method, and adds that th [illegible] of the lesion renders total castration imperative He considers closing the vaginal vault and the pelvic peritoneum a marked improvement in technique, and that it should be done in every case unless there is some special contraindication

Jacobs (Brussels) prefers posterior and anterior colpotomy in cases of extraperitoneal cellulitis, and uses the thermo cautery to make the incision, thus avoiding infecting the vagina with the pus which escapes and may cause post operative accidents In performing hysterectomy he substitutes ligatures for the forceps, and since he has done this he has had no post operative intestinal occlusion nor peritonitis Drainage is not required after a radical operation, except when pus has escaped into the peritoneum

Acconci (Genoa) prefers vaginal hysterectomy when the indications allow a choice

Coromilas (Calameta) reported a case of pelvic suppuration caused by malaria and cured by quinin

Laroyenne's method of vaginal *débridements* was described by him and its advantages confirmed by Adenot It is more conservative than laparotomy or hysterectomy, while it reaches pus sacs inaccessible by any other method, and makes an opening large enough to empty them and keeps it open long enough to be really effectual Laroyenne's trocar invented for the purpose is convenient and sure, but is not absolutely necessary Doyen compared his operation with Péan's with an argument for its superiority It consists in opening the posterior peritoneal cul de sac, and freeing the posterior surface of the uterus from the adherences, if there are any, and then extracting the organ by inverting it to the vulva, after median hemisection of its anterior wall, afterward extracting the adnexa Hemostasis is unnecessary during the course of the operation, and forcipressure of the broad ligaments is only required afterward, and above the adnexa (The *Bulletin Medical* of September 6, describes the Doyen method in detail)

Reynier appealed for a more rational and eclectic treatment, based upon the indications, which should be more definitely established His record since 1891 is 200 operations for pelvic suppurations In four cases, with four recoveries, he opened the pus sac by the inguinal and subperitoneal route for phlegmons of the broad ligament after childbirth In 110 cases he opened the abdomen, with 9 deaths, 7 from peritonitis, 1 from shock and 1 from hemorrhage He has performed vaginal hysterectomy 52 times, with 6 deaths, 1 from hemorrhage, 1 from shock, 2 from intestinal occlusion, and 2 from peritonitis In 46 cases he opened and drained the pus sac through the posterior cul de sac, with no deaths, but in 9 cases consecutive hysterectomy was required and laparatomy in 4 His experience has convinced him that almost all pelvic suppuration can be approached by the abdomen, and that our methods of draining render the danger of infection much less than the hysterectomist extremists are willing to admit In case of a young woman with symptoms of recent infection and evidences of pelvic suppuration prominent in the vaginal region, he first makes an incision in the posterior cul de sac with large drainage If in spite of this, the phenomena of infection continue, he completes the operation with a hysterectomy if the uterus is diseased, but if not, he prefers a laparotomy His indications for primary hysterectomy are uterine abscesses opening into a neighboring cavity, especially into the rectum Also old salpingo ovaritis, with pelvi peritonitic complications which have produced a diffuse mass walling in the uterus, and also for fibromatous uteri complicated with pus in the pelvis In other cases he is inclined to prefer laparotomy, especially in cases of doubtful diagnosis

Pichevin (Paris) has found sclerotic lesions in removed retrodeviated uteri, and has also produced similar lesions in rabbits in ths same way

In discussing the question of surgical treatment of retro deviations of the uterus, all seemed to agree that massage and the pessary should be tried first, and the metritis and all other complications receive careful preliminary treatment, which often puts an end to the displacement without an operation Polk (New York) disapproves of fixation, and restores the uterus to position by shortening the round ligaments through an opening in the anterior vaginal cul de sac He sutures the ligament a certain distance above its base, with its peritoneal covering, to the uterus on a level with its base, leaving a couple of loops One of these he sutures to the uterus, and the other to the ligament above the first suture At the same time he shortens the sacro uterine ligaments when necessary, through a transverse opening in the posterior cul de sac, at the utero vaginal insertion A strong silk suture is then placed at each sacro uterine ligament at a median point, the ends brought through the vaginal wall at the extreme corners of the incision and tied firmly together, catgut closing, drain removed in fifteen days, patient kept in bed three weeks, no pessary but supervision of urinal and intestinal functions and ventral belts for patients with prominent abdomens

Pozzi (Paris) proposed to substitute the term "excessive movability" for movable retrodeviation He treats it with the pessary and hypogastric belt, curing the metritis (curettement, amputation of the cervix, etc) and restoring rents in the peritoneum by an extensive plastic operation He considers a retrodeviation with adherences a secondary symptom, and treats it by finding and removing the diseased tubes or whatever the cause may be

Byford (Chicago) outlined his cysto hysterorrhaphy as a T-shaped incision in the anterior wall of the vagina, separation of the adherences, suture of the fundus to the vesical peritoneum, shortening the round ligament through the vagina and closing with transverse sutures that draw the tranverse incision into the median line

Schmeltz (Nice) prefers anterior colporrhaphy (simple incision in the mucosa, enlarging it with the fingers), combined with hysterectomy (ligatures) and perineorrhaphy

Jacobs (Brussels) reports four successful pregnancies in twenty one cases treated by fastening the anterior uterine wall to the upper part of the peritoneum of the anterior vaginal cul de sac He announced that the later results of other operations, inoffensive in themselves, may prove very dangerous and exhibited some pedicules that had formed between the abdominal wall and the uterus causing death from ileus, etc

Engstroem (Helsingfors) reports eighteen ventro fixations of movable retro deviations and thirty four of fixed All successful A single suture is passed through the abdominal wall, the peritoneum and the fundus This leaves the uterus with almost normal movability

Hartmann (Paris) has found that the development of the fetus brings the pregnant uterus into place, assisted by vaginal manipulation, except where there are adherences between the bladder, omentum and rectum, which require laparotomy, but such cases are rare

Mangin (Marseilles) has failed with the Alexander or Nicoletis operation alone, but has been successful every time when they were combined with plastic operations His advice is, first, pessary for movable retrodeviations This failing, vaginal colpo hysteropexy with plastic operation on the vagina He limits the Alexander and abdominal hysteropexy to patients with non resisting tissues Complications must be cured with medical treatment, plastic operations, etc , as may be necessary, and if the condition of the appendages requires it, laparotomy when the lesion is single, hysterectomy if double

The majority of speakers deprecated the use of fixation, as it rendered after pregnancy so dangerous, especially vagino fixation, although the operation is a good one after the menopause Doyen's method of treating painful retrodeviations differs from all the preceding and, as he claims, has none of their disadvantages He performs the Alexander operation and also shortens the anterior uterine wall, thus avoiding the dangers of suspending the uterus from any one point, and limiting the operation practically to the uterus itself The cervix is seized with two clamp forceps, as if for a hysterectomy, and drawn down to the vulva The uterus in this position, an incision is then made in the interior cul de sac of the vagina, the bladder is detached and an opening made into the anterior cul-de sac of the peritoneum A silk thread is then passed transversally through the superficial coat of the fundus with a special needle holder The other end is fastened in the lower part of the subvaginal portion of the cervix This ligature shortens the anterior uterine wall and draws the organ into an upright position without interfering in the least with the direction of the cervical passage A second ligature is made above it to strengthen it, and the vaginal wound is closed with a silkworm gut, the two ends simply held by a rubber tube The entire operation requires only five or six minutes It is completed by shortening the round ligaments 8 to 10 centimeters, through an incision into the anterior wall of the inguinal canal

Reynier performs hysteropexy by putting his threads into the broad ligament, and passing them under the uterine insertion of the round ligament, fastening them on each side to the abdominal wall In every case the uterus has retained its position

Schwartz (Paris) reports several successful pregnancies after his hysteropexy After preparing the patient for laparotomy and introducing a Hegar bougie (6 or 7) into the uterus, held in place with a cotton tampon, he incises 4 to 5 centimeters, and explores with his finger the condition of the appendages, while an assistant straightens the uterus by gently pushing up the bougie into it After the adherences are detached, a silk thread (No 2 or 3) is passed through the uterus below the emergence of the two tubes The loop thus formed serves to draw the uterus up and allows two or three other threads to be taken below it, avoiding the vesical cul de sac, and keeping as far from it as possible If the appendages are diseased, they are ignipunctured, resected or removed, before the threads are fastened, after being passed on each side through the entire thickness of the wall, except the skin and the subcutaneous cellular tissue Separate threads close the peritoneum, the teguments, and the muscular aponeurotic planes He has only had two relapses, one of them after confinement, two still suffer pain, thirty are definitely cured

SELECTIONS

A Case of Compound Protozoan and Bacterial Infection—The patient, A J , was a Pole about 29 years of age, from whom a satisfactory history could not be obtained He had been living in a malarious district since March of the past year (1895) but he had been quite well until three weeks prior to his entrance, which was on October 21 His illness began with diarrhea, which rapidly assumed a severe character, the movements containing much blood and mucus During these three weeks he stated that he had several times experienced slight chilly sensations and also felt feverish On entrance to the hospital he was very anemic, extremely sallow, had a palpable spleen, slight fever and severe dysentery, the movements showing much blood and mucus The dejections contained many motile amebæ having the appearances of the ameba coli The blood examinations showed hyalin bodies and crescentic and ovoid pigmented forms of the malarial parasite Under the administration of five grain doses of quinin every three hours the temperature fell The diarrhea was treated with irrigations of quinin (1 1500) repeated twice daily, but without apparent effect The patient continued to lose blood per rectum and died on November 2

The *autopsy* was performed seven hours post mortem Body of a moderately strongly built, much emaciated man The surface presented a distinctly sallow hue The mucous membranes of the mouth and conjunctivæ were extremely pale The abdomen was moderately distended, the subcutaneous fat almost absent, the muscles dark brownish red in color

The peritoneal cavity—The omentum was well spread out, covering the intestines, but it presented an opaque appearance and was covered with a sticky exudate The loops of the moderately distended small intestine were glued together by a similar sticky exudate The serous membrane itself was in places vividly injected In the fossæ small accumulations of fluid containing flakes of fibrin were encountered The omentum was adherent along its lower border to the much enlarged and inflamed appendix vermiformis The appendix lay anterior to the cecum and between it and the anterior abdominal wall, it was provided with a mesentery which reached within 3 cm of its tip, and at the termination of this the appendix was bent sharply upon itself, giving rise to a right angle The distal 3 cm of appendix was the least dilated part, the remainder had the thickness of the index finger and presented in addition three bulbous enlargements, which on section were found to correspond to areas of necrotic tissue The whole was embedded in a sticky, opaque exudate

Intestines—The large intestines were greatly distended The sigmoid flexure was of rigid consistence and projected beyond the pelvic brim Within this portion for a distance of 2x5 cm the serous coat was infiltrated with blood and presented a necrotic appearance On opening the large intestine the entire mucous membrane was found in a frayed and sloughing condition, opaque, everywhere infiltrated with gelatinous pus and evidently necrotic The necrosis seemed to extend far beyond the mucous coat and to involve the deeper layers The walls, as a whole were very much thickened In many places coagula of blood were discovered Amid this general necrosis and sloughing more circumscribed ulcerations existed, some of which seemed to reach to the peritoneal coat These in particular were surrounded by thickened and purulent margins, and at times they definitely undermined the adjacent tissues The ulcerations and sloughing extended from the rectum to the cecum, involving the whole of the latter, penetrating into the appendix, but ending abruptly with the ileo cecal valve The small intestine was entirely free from ulceration, and it showed throughout nearly its whole extent, although most prominently upon the crests of the valvulæ conniventes, a slaty pigmentation The duodenum was more pigmented than other parts of the small intestine

The *spleen* was enlarged, weighed 380 grams, its capsule was wrinkled, and on section it presented a bluish black color In consistence it was almost diffluent The Malpighian bodies appeared enlarged, the pulp increased

The *liver* weighed 2100 grams, its color was dark and slaty Small grayish white nodules could be seen on section, which varied in size from a pin point to a hemp seed The larger ones could easily be made out to be abscesses, the contents of which were opaque, gelatinous and pus like The wall of the *gall bladder* was thickened and infiltrated with a similar exudate to that covering the peritoneum The mucous membrane was, however, intact The remainder of the organs exhibited no remarkable lesions

Microscopic examination of the fresh specimen—Attention was first directed to the study of the exudates for amebæ, and for this purpose pus, *a*, from the peritoneal cavity, *b*, from the intestinal contents, *c*, from the liver abscesses, was employed The most painstaking search failed to reveal amebæ in the pus from the peritoneal cavity, while on the other hand many typical living and moving amebæ were discovered in the pus from the ulcers in the large intestine and the intestinal contents and a smaller number in the contents of the liver abscesses

The exclusion of amebæ from the peritoneal exudate led next to the staining of cover slips for bacteria By the use of ordinary staining agents (gentian violet, methylene blue) myriads of capsulated diplococci resembling the micrococcus lanceolatus were revealed The contents of the liver abscesses, stained in the same manner, failed to show any bacteria whatever The microscopic examination of the abscess contents indicated that fewer pus cells and more necrotic and disintegrating liver cells composed these than in ordinary abscesses, thus recalling the fact pointed out by Councilman and Lafleur in their monograph on amebic dysentery, that true suppuration is not caused by the ameba dysenteriæ

The source of the bacteria found in the peritoneal exudate and which evidently were the cause of the acute peritonitis, was sought in the intestinal contents, where, as is well known, they are not infrequently contained, and from which source, as we have previously pointed out, they may invade the peritoneum and set up a fatal peritonitis The condition of the appendix vermiformis, which arrested attention from its swollen and necrotic appearance, was believed to have led to the escape of the microorganisms in question Upon closer examination it was found that corresponding with the dilatations previously described, the entire wall was in a necrotic condition The ulcerations themselves reached deeply into the inner coats, but did not penetrate all the coats The lumen of the swollen appendix was filled with yellow, gelatinous pus quite resembling that found in the peritoneal cavity itself Cover slip preparations showed many encapsulated diplococci besides several kinds of bacilli The former much predominated in numbers

Malarial bodies were not numerous in smear preparations from the organs, although pigment was abundant However a few undoubted ovoid bodies were found in the smears from the spleen and bone marrow

Cultures—Petri s plates were made from the blood in the heart the exudates and all the organs upon from the *heart's blood, spleen, lungs* and *liver abscesses* showed no growth after having been kept at the temperature of the thermostat for forty eight hours

Peritoneum —The plate was crowded with colonies, apparently of two kinds, which, owing to the large numbers, probably did not reach full development The larger colonies consisted of bacilli which were identified and shown to be the bacillus coli communis The smaller colonies (predominating) were made up of oval diplococci which were shown (cultures and animal experiments) to be the micrococcus lanceolatus The plate made from the *bile* contained 7, from the *liver* 30 colonies of the bacillus coli communis The plate from the *kidney* was crowded with colonies of the colon bacillus, among which a few smaller colonies of diplococci were found, these being the micrococcus lanceolatus

Histologic examination —The microscopic examination of the hardened tissues was confirmatory only of the features of the case as already described Nothing new was discovered As regards the malarial pigmentation, the dark pigment was found especially in the liver and spleen (bone marrow not studied), and in these organs in the usual situations The parasites themselves were very difficult of demonstration The lesions in the large intestine caused by the invasion of the amebæ were perhaps the most interesting The necrosis, it was found, extended into, but for the most part not through the innermost muscular tunic, but it was surprising to what extent the mucous membrane might be dissected away from the submucosa without losing its vitality Not a small part of the frayed appearance presented by the large intestine was produced by this partial dissection of the mucous coat The bases of the ulcers proper were formed for the most part by the circular muscle, which was itself infiltrated with inflammatory products, cells, serum, fibrin The inflammatory infiltration extended into the depths of the tissue, often to the serous coat, and spread laterally for a great distance It seems probable that the ulcers in the appendix originally were caused by amebæ, and that subsequently the extension of the necrosis to the serous surface was the work of the micrococcus lanceolatus

Amebæ apparently were abundant But, just here it is proper to state that in the hardened tissues it would be easy to be led into error in regard to the significance of many of the ameba like cells present From a study of the transitions of connective tissue cells and their progeny in the chronically inflamed parts, it is quite certain that many of the bodies resembling amebæ are swollen and degenerated (fatty or vacuolated) tissue cells These, too, often lay in definite spaces, and they were found in the submucosa and muscle and within small veins Without the proof supplied by the examination of the intestinal contents during life and at the autopsy, one must have remained in doubt as to the presence of amebæ among these elements

The kidneys showed a moderate degree of parenchymatous degeneration In addition to this, emboli of liver cells were detected in branches of the renal vein Similar emboli were discovered in the central veins of the liver lobules not infrequently Lubarsch has reviewed the literature upon the subject of "parenchymcell emboli" It appears that liver cell emboli are either of traumatic or of infectious (or due to intoxication) origin There is no definite relation between the extent of the injury and the occurrence of such emboli The transported liver cells, besides being found in the veins of the liver, occur in the heart, pulmonary arteries and branches of the renal and hepatic arteries Among the infectious diseases liver cell emboli are found very often in eclampsia and chorea In eclampsia they are found very often in the arteries of the lungs and brain and in the renal veins, in chorea in the hepatic artery and branches of the portal vein (patent foramen ovale) Where hemorrhage, necrosis and softening exist, liver cell emboli are encountered Thus they have been found in scarlet fever, in softening of hepatic gummata and in liver abscess The transported liver cells have been found followed from the hepatic veins into the coronary, renal and other arteries Their occurrence in veins—renal and cerebral—is attributed to retrograde embolism for which a high degree of venous stasis, such as occurs in eclampsia, has been assumed Evidence of such stagnation is wanting in our case On the other hand the disintegration of liver tissue such as has been found in other cases, is supplied by the abscess formation and circumscribed necrosis in the liver Lubarsch states that the conveyed liver cells may persist from three weeks to two and one half months, but evidences of proliferation have never been observed —Reported by Dr Simon Flexner in *Bul of the Johns Hopkins Hospital*, September and October

Foreign Bodies in the Esophagus —Dr Carl Beck of New York in the *Clinical Recorder* argues for an earlier employment of surgical treatment in these cases His experience shows that valuable time is generally wasted by the administration of emetics and covering (einhullende) substances, such as soft bread or hashed potatoes, until even successful removal by surgical procedures is not able to prevent the fatal outcome any more It is justifiable to attempt once to remove the foreign body by administering an emetic But if this *one* effort fails, either extracting or pushing down should be done without further delay All bodies which can either be seen or which can be felt by finger or explorer, within the pharynx, must be extracted If the body has passed the isthmus, it has to be pushed down into the stomach, sharp edged bodies, however, like splinters of bone or wood, needles, pins, etc, to be excepted Repeated attempts should be made to extract such bodies also, because they may perforate into important blood vessels or the trachea, or may cause fatal abscess formation The best instrument to be employed for such purposes is a so called "coin catcher," which consists of a long flexible sound made of whale bone To one of its ends a piece of sponge is attached for the purbose of propulsion toward the stomach, on the other end is a grooved metal ring By passing the foreign body first with this grooved ring and then withdrawing it slowly, at the same time turning the instrument slightly, the body is caught in the groove in the great majority of cases The coin catcher is introduced best after having it lubricated with the white of an egg The patient's head is thrown back so as to bring the axis of the mouth and pharynx in line with the esophagus (just like the juggling sword swallowers) The location of the body will then be indicated by the stoppage of the instrument If such methods of fishing up or pushing down do not avail, esophagotomy must be performed without delay Herniotomy does much less harm to a strangulated gut than a prolonged taxis, and the same principle and view applies here Esophagotomy is by no means a difficult operation, if only the principle is obeyed to operate with blunt instruments After having introduced a sound into the esophagus from the mouth as a guide an incision is made alongside the left anterior margin of the sterno cleido mastoid muscle Then the tissues containing the carotid and jugular and the pn vagus, together with the ramus descendens of the hypoglossus nerve can be separated without any cutting by the use of the Cooper scissors and then be retracted with blunt hooks Now it is easy to feel the sound, previously, and to incise on it After the foreign body is extracted with a suitable forceps, a sharp spoon sometimes also being useful, the wound is but partially closed and the remainder packed with iodoform gauze At the New York German Medical Society (see *New York Medicinische Monatsschrift*, April, 1892) Dr Beck presented a case of a girl, 18 months of age, in whose esophagus a quarter of a dollar piece had remained for four weeks and which he could extract by the coin catcher, the patient making a good recovery But such cases are only the exception Repeatedly he has seen cases in which all the various means of extraction and propulsion were tried, and only after much valuable time was lost esophagotomy was resorted to But the extraction then would not avert septic inflammation and its consequences (broncho pneumonia, etc) The Roentgen rays seem to have started a new era in the location of foreign bodies in the esophagus, so that they will not remain unnoticed any more, and are no longer confounded with phthisis pulmonum, croup, bronchitis, asthma, etc J W White (*University Medical Medicine*, June, 1896) could get a definite information by the rays in a successful case of a girl, 2½ years old, which had swallowed a jackstone the location of which being such that gastrotomy appeared to be preferable to esophagotomy

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE INCLUDING POSTAGE

Per Annum in Advance	$5 00
Single Copies	10 Cents

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 61 Market Street (Occidental Buildings) Chicago, Illinois

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association, Dr Henry P Newman, Venetian Building Chicago, Ill , sending him a certificate or statement that the applicant is in good standing in his own Society signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association *is not necessary to obtain membership*

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character intended for publication in the JOURNAL, should be addressed to the *Editor*, and all *communications relative to the business of the* JOURNAL proof sheets returned or in regard to subscriptions should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION 61 Market Street (Occidental Buildings), Chicago

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL

INFORMATION WANTED

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second class mail matter not having street address would be placed in the general delivery to await call

SATURDAY, OCTOBER 17, 1896

THE TREATMENT OF INSANITY EIGHTEEN CENTURIES AGO

Nowhere in science is the truth of TENNYSON, that

> "The course of time will swerve,
> Crook and turn upon itself in many a backward
> streaming curve"

better illustrated than in medicine All great medical discoveries seem upon the point of being made long ere the culmination of facts places them beyond destruction by inertia and conservatism Anesthesia, the germ origin of disease, antisepsis and multitudinous "late" discoveries were discernible for centuries in medical works ere the nineteenth century placed them in the rank of commonplace facts This is peculiarly true of psychiatry, whose essential principles were outlined eighteen centuries ago Much suffering might have been saved the hapless insane and much misfortune to the medical profession been avoided had these principles then outlined been adopted in the main According to SORANUS (A D 95, whose writings are recognized as those of CÆLIUS AURELIANUS, his translator), it is useless to examine into causes, as different causes may produce analogous effects It is only necessary to know the results in order to apply suitable remedies He was decidedly averse to violent emetics and purgatives He everywhere manifests the fear lest inflammation should be augmented by the strength of the remedy He advises frequent exercise, warm fomentations, inunctions, cataplasms, fumigations, frictions, diet, baths, leeches and cuppings He recommends great attention to the character of the air, whether moist or etc He rejects all empiric medication and fetichistic formulæ The maniacal should be placed in rooms moderately light, of a moderate temperature and whose tranquillity should be uninterrupted by noise No painting should ornament the walls The air should come in by elevated openings The patients should be placed on the ground floor rather than on the upper story, as most of them are disposed in their paroxysms to cast themselves down Their beds should be solidly fixed and so disposed that the patient may not see persons entering, nor be irritated by a variety of figures If they be so agitated that it is not possible to give them aught to lie upon except straw, this should be well selected, prepared and stripped of everything hard, in order that it may be mild and not disagreeable to the touch If some parts of the body have suffered from the movements of the patient, use warm applications and fomentations of oil mixed with decoctions of fenugreek, mallow or flaxseed Frequent passing in and out should be forbidden Sometimes use an intentional indulgence and sometimes a slightly severe reprimand, with an explanation of the advantages occurring from a better course of conduct If agitated difficult to restrain, or irritated by solitude, it is necessary to have supervisors who should be ordered to master the patients without their perceiving it, approaching as if to make friction in order never to provoke them, if the sight of men irritates, and only in very rare cases he employs ligatures, but with the greatest precaution, seeing that the bonds are of a soft, delicate texture Means of repression employed without discretion augment and even create fury instead of lulling it (GALT's Insanity, 1846) If they have fear and respect for any one person they should not see him often, frequent visits compromise such an ascendency But when they resist the wishes of those around them it is necessary to recur to his authority If light excites them, their eyes must be deprived of it, though not the rest of the body

Abstinence is suitable at first and recourse to bleeding if the strength permits If no contraindication exist it should be repeated from time to time One of the best means of appreciating the degree of the strength is drawn from the state of the pulse which the physician must observe whether it is strong or feeble SORANUS should commence feeding with great precautions and not permit any except very light diet of easy digestion The patient must be thus nourished during the decline of the affection Injections must not be neglected if the evacution be not regular in a great number of cases the belly should be covered with emollient cataplasms which descend to the pubis in ord [illegible] may [illegible] any pain which the he [illegible]

Physi [illegible] s should [illegible] nd have ence of moral impressions, gay ideas and those things causing some relaxation of mind If the disease remains stationary he shaves the head Scarifying cups should be applied in turn to the breast and between the shoulders as connected with the head But these applications ought not to be too near the head nor too largely made, as calling the blood in this quarter, etc Leeches may be placed on the forehead or the temples, taking care to favor the flow of blood by cataplasms of emollient substances or sponges dipped in water If the symptoms persist, the same means must be used the second or third day and as often as necessary If the parts covered by the cups and the leech bites be painful they should be moistened either with oil or a decoction of mallow, etc If the disease arise from fatiguing overwatching, it is necessary to have recourse to rides upon a bed suspended or upon a chair carried along or even upon enlaced hands The monotonous noise from the continual fall of a small current of water from a height has good effects Application of warm sponges upon the eyelids is also useful When the paroxysm declines it is necessary to give more varied aliments, moderately strengthening when they have regained their strength

Exercise is then especially beneficial They must, also exercise the voice They should be made to read writings containing faults, which often at the same time have the advantage of exercising the mind in the correction of imperfections in style These writings should be of easy comprehension The physician should converse with them, asking questions without fatiguing them Recourse should be had after reading to theatrical performances, the recreation from which will diminish a sadness ready to awaken, or frivolous fears ready to reveal themselves At a more advanced epoch of treatment, occupy the patients with weighty meditations and discussions in order to give their mind its full capacity, but with the precaution that the commencement of the subject treated should be without warmth, that the narration, on the contrary, and the demonstration should be clear and complete, should solicit an animated utterance and that the epilogue should be brief and careless His hearers should give the patient their benevolent approbation After this exercise they should promenade or have their bodies rubbed As to the unlettered the physician should discuss with them matter only relative to their conditions He should speak to the laborer concerning agriculture, to the mariner as to navigation If we have to act with a man ignorant of everything he should present very general subjects or a series of numbers Physicians are able in truth to find suitable nourishment for all sorts of minds, but above all should agreeably complement the patient Annointing and frictions which have been recommended should be made at first upon the shoulders and on the neck, commencing lightly, then more strongly afterward on the head, after which a bath The nourishment should become more and more substantial After beans, herbs, then fish, the brains of different animals, an easily digested aliment, then little birds The larger kind later as thrushes and young pigeons There should be even more reserve as to the hare and the roebuck

Physicians should grant a little weak and light wine, at first every five days, then four, three, even until every day When no new symptoms occur and the patient has become much less impressible, change of air will be of great advantage Voyages by sea or land, distractions of all sorts, recreation of the mind, agreeable, affectionate conversations will produce an excellent effect, for if ennui and sad feelings act on the sane, how much will they influence the scarcely cured? The convalescent, should he desire it, can hear the precepts of the philosopher They often dissipate sadness, fear and excitement and may contribute powerfully to the reestablishment of health If the malady really persists and not merely some of its symptoms, a return is counseled to the previously mentioned means, to exposure of the body to the heat of the sun, the head only being free from its action, to sinapisms and to violent exercise of different kinds

Soranus combats his predecessor's recommendation of darkness in all cases, because it may suit one and not another, and their recommendations of an immoderate abstinence without exception, because this may sometimes throw the patient into fatal feebleness and prevent the use of means otherwise suitable They seem, he says, to consider their patients as ferocious beasts to be lulled by hunger and thirst, and led by the same error they wish to chain them cruelly, not considering that it is more convenient and easy to restrain by the hands of men than by violence and the lash, a deplorable treatment which can but aggravate their condition and make bloody their limbs and offer the sad spectacle of their misfortune at the moment in which they regain their intelligence By medicaments, as the poppy, they provoke a morbid torpor instead of good sleep They rub the head with oil of roses, etc , and excite organs needing relaxation They make little judicious use of cold, ignorant that it is often excitant They employ irritant clysters and thus produce dysenteries They counsel drunkenness and love, which are causes They prescribe music as a routine, whereas it sometimes excites The generative act should not be permitted to the insane The repression of their desire may sometimes agitate them, but they are oftener found to be worse after coitus His treatment of melancholia has been indicated in what has been said of mania

This treatment of insanity was far in advance of that practiced in Europe in the first decades of the present century, or that of Cook County in 1871, of Auburn (N Y) in 1876, of Anchorage (Ky) in 1882 and of 1896 by the Hahnemanniacs at the Norfolk (Neb) Insane Hospitals Whips, violence and excessive restraint were the therapeutic methods employed at these institutions, not spasmodically or furtively, but on a settled principle Soranus, long ere Pinel, Rush, Tuke, Conolly or Gardner Hill, seems to have grasped in the main the true principles of psycho-therapy

THE PROGNOSIS OF MANIA AND MELANCHOLIA

The common notion taught in all text-books and held as one of the axioms of practical psychiatry, that mania is the most hopeful and curable form of mental disorder, will receive a severe blow from the lately issued fifth edition of Kraepelin s "Psychiatrie " The author of this volume, one of the best known and admittedly one of the ablest of German alienists, has very largely remodeled his work, and it contains the latest and fullest results of a very wide experience, estimated with a thoroughly critical and competent judgment His conception of mania is not essentially different from that generally accepted by authorities on mental disease, but he does not recognize it as an independent entity in his classification All cases, according to him, especially those in the earlier and middle periods of life, before the downward slope of life has been reached, are properly to be referred to the periodic insanities, they are not single, isolated attacks of a disease that may never be again suffered from, but are indications of a constitutional disorder, sure in time to recur He bases this opinion on an observation of a thousand cases carried over a great many years, and in all these he has found but one in whom the disorder did not recur and that is not in support of the view stated above A single exception in such a series only proves the rule, and so far as known no one has ever followed up as methodically and carefully the after-histories of his patients as Kraepelin seems to have done It has been a matter of general experience that an attack of mania was perhaps, as we may say, one of the least self protective of disorders, that a second attack was very liable to occur after a variable lapse of time but few, if any, had before been led to generalize from these facts that it is properly to be reckoned a periodic disease Kraepelin himself admits that the interval of mental health may be long—ten years or even more in some cases—but he claims none the less the validity of the rule he has laid down that recurrence is inevitable, sooner or later

It may be thought, perhaps, that this is merely a change in the point of view, that the facts are the same, but that they are differently estimated by him from those who have written before It is, however, really much more than this if we accept Kraepelin's views, our prognosis of mania and of the so called simple insanities generally is completely reversed, instead of being the least, they are to be counted amongst the most formidable types of insanity as regards the future of the patient What is true of mania is true also in regard to melancholia, which he classes amongst the mental disorders of the period of involution when it occurs in early life it also falls in his system into the periodic insanities

How generally Kraepelin s views will be accepted is an interesting question His authority is certainly of the highest, and his method by which he reaches his conclusions, the careful and thorough research into the after-history of his patients, gives them the very greatest weight The fact that he was able to follow the careers of a thousand cases of mania after discharge shows the range of his clinical observation far exceeding the possibilities with many of his less favored co-workers in this department It will be, nevertheless, with something of a strain, that alienists will give up their time-honored views to take up others, new and altogether different from those they have been accustomed to hold The publication of these, however, will undoubtedly excite fuller anamnestic research in all quarters, and thus prove a most valuable stimulus for work in a direction that has perhaps been hitherto too much neglected It will also lead to a more careful diagnosis and scrutiny of individual cases, and the separation of the exhaustion and toxic types from those that fall more properly under the class considered by Kraepelin There is no doubt at all that cases of confusional insanity are very often diagnosed as mania, as pointed out by Dr W L Worcester, and the same is true of the post-febrile, toxic and exhaustion deliriums Excluding these, it may very possibly be true, as Kraepelin holds, that mania and melancholia are indications of constitutional taint and incurable disorder

THE SMOKE NUISANCE, A FABLE

The editor of the *Glasgow Sanitary Journal*, August, seeks to show in fable that the abolition of smoke nuisances is a possibility He places his chief reliance upon the developments of science, giving experience the go-by, saying

One day Experience, Inexperience and the Scientific Mind met at a congress and shook hands They began talking about the weather

"What a beautiful morning!" exclaimed Inexperience

"Wind in the north, said Experience "It will be rain by evening '

"Then we shall see the rainbow,' said the Scientific Mind

"I wonder said Inexperience, "when we shall control the weather, like the man in Rasselas

"Never," said Experience "The thing is a demonstrated impossibility

"And yet ' gently, as to himself, said the Scientific

Mind, "but yesterday I first spoke to the antipodes, but to-day I listened to the stored voices of my dead, but even now, I have seen with these eyes the cast shadows of the skeletons we are within the flesh To-morrow, what shall I not see and hear?"

"Yes, yes," said Experience "The telephone, the phonograph, the X rays, and all that But that sort of thing can not go much further, there is not much more to know, else we should know it"

"On the contrary," said Inexperience, "we know nothing yet, comparatively"

"*You* speak for yourself," said Experience

"For us all!" said the Scientific Mind, humbly

"How?" inquired Experience, surprised

"As thus," said the Scientific Mind "Glasgow is sick with fog, which is a cloud, which is the rain Why? Glasgow burns coal, which is smoke, which makes the fog blanket, which slays the sunlight, which is health"

"That's old news," said Experience "But what do you propose to do?"

"Burn coke," said the Scientific Mind

"I never thought of that," said Experience

"Of course not," said Inexperience "Who said you did?"

"Think of it now," said the Scientific Mind

So they shook hands again and went their ways

We might add that in all human probability coke was *not* accepted by any considerable number of the people, and the smoke and black fog continue to have it all their own way

A MEDICAL SATIRIST OF MEDICINE

Medicine in France in the seventeenth century was the peculiar theme of satire, probably for the same reason it is a safe mark for newspaper sarcasm to-day The sensation mongers who dare not attack the rupture-curers, advertising quacks, patent medicine men or abortifacient mongers, openly assail medical men on the ground that it amuses the public and does not hurt medical science Precisely the same regard for the sacred cash box prevented the French satirists from attacking the despot Louis XIV and caused his brutal aristocracy and plutocracy to concentrate their venom on the physician Moliere was an expert in this He had a quasi-medical predecessor to whom he was probably much indebted Bertrand Harduin de St Jacques (1598—1648) entered upon the study of medicine at the University of Montpelier For unusually outrageous contempt of the boundaries of property, he was expelled and became first a travelling quack and then naturally gravitated into a strolling player He came to Paris and under a false name, entered the Bourgogne theater troupe where his satire against medicine was so renowned that Moliere, then a youth, was brought to the theater by his grandfather to see St Jacques play The Paris physicians took the satire good humoredly and were often auditors After eight years of Paris stage life, St Jacques obtained a medical degree through the influence of Cardinal Mazarin, and thenceforth practised medicine reputably till his death St Jacques had something of the degenerate in his make-up, for "He was a large brunette with dark sunken eyes and flat frog nose, who resembled a huge monkey and did not even need a mask on the stage, as he wore a natural one"

ANOTHER DONATION TO THE NEWBERRY LIBRARY

Professor De Laskie Miller of Chicago, has given his entire collection to the Newberry Library It was one of the most complete private collections in the city, not made up of periodicals and miscellaneous books, but composed of standard works of all the best authors from the earliest times to the modern, such a collection as a teacher desiring to keep abreast of the times would naturally purchase

The library contains about 600 volumes of carefully selected standard works Those relating to obstetrics and diseases of women and children, are noticeable

Such libraries as these, like keen tools in the hands of the master workman, are valuable as a whole not merely on account of the intrinsic merits of the component parts The books when selected in this way by a skilled hand, have a reference to each other as close and enduring as the inlaid pieces of a Florentine mosaic

But to use books rightly one must know them The elder D'Israeli said that one might as well fill a room with musical instruments and expect to be an expert musician by mere contact, as to expect a man to become a literary man by the mere possession of books And so we must turn to the great libraries for the production of our future literary men, and when the right man, comes in contact with the working collection of a worker in his profession, we may expect great results

WASHINGTON AND HIS PHYSICIAN'S BILL

Physicians who are drawing pessimistic auguries from the difficulty with which collections are made during the present year, may take some comfort from the fact that, on the eve of the first election for President of the United States, the financial difficulty was such as to affect George Washington the Father of his Country, the unanimous choice of his countrymen for President, in the payment of his physician, Dr Craig In a letter to the latter dated Aug 4, 1788, Washington says

"With this letter you will receive the horse I promised you, and which I now beg your acceptance of He is not in such good order as I could wish, but as good as my means would place him I also send you thirty pounds cash for one year's allowance for the schooling of your son G W I wish it was in my power to send the like sum for the other year, which is now about or near due, and that I could discharge your account for attendance and ministerings to the sick of my family, but it really is not, for with much truth I can say I never felt the want of money so sensibly since I was a boy of fifteen years old, as I have done for the last twelve months and probably shall do for twelve months to come

"Sincerely and affectionately, I am yours, etc,
"George Washington"

PUBLIC HEALTH

Typhoid in Columbus, Ohio—All physicians of this city are required to report the presence of typhoid fever within twelve hours after having become advised of it Such is also the rule in cases of smallpox, scarlet fever and diphtheria

The Pennsylvania State Quarantine Board—This Board met in Philadelphia October 5 Dr Boening the State Quarantine physician reported for the month of September as follows Number of vessels permitted up from quarantine during the past month 94, all of which were in good sanitary condition These vessels were classed as follows Steamships, 57, schooners, 19, barks, 15, brigantine, 1, ships, 2 They were laden as follows Single cargo vessels, 49, general cargo vessels, 25, water ballast, 17, solid ballast, 3 Of the foregoing vessels 18 carried passengers, with a total of 1771

Measles and Diphtheria in Sioux City—The city is threatened with an epidemic of measles At least that is the opinion expressed by Health Officer Dr J M Henry The Doctor when the first case was reported a few days ago looked it up thoroughly as it is something unusual to have measles at this time of the year and it is regarded as a serious matter With the cold weather coming on he says the disease, however slight, may develop into catarrh, bronchitis and lung trouble The Doctor found that the child had been attending the Jennings street school until the day it became so sick that a physician had to be called Several other cases were immediately reported after the first one, and the Doctor attributes them to the exposure to the first case, as the children all attended the same school He says that parents should exercise more precaution and not send their children to school when they know them to be sick or threatened with some disease Some people are of the opinion that the quarantine is not so important in a case of measles but the Doctor says it is just as rigid as in a case of smallpox and if the parents do not pay attention to this fact they will be dealt with according to law Aside from the measles several cases of diphtheria have been reported to the health officer from different parts of the city A diphtheric child rode in the conveyance provided by the school board for carrying children from the outlying districts northwest of town to the West side and an epidemic is feared At the suggestion of Superintendent Kratz the conveyance will not be run for several days until there are some new developments and the children will thereby be given a holiday —*Sioux City* (Iowa) *Tribune*, Oct 3

An Epidemic of Fevers—Diphtheria was reported to the Iowa State Board of Health yesterday at Dubuque, Conway and Blockton, Taylor county, Downs, Wright county, Fertile, Worth county, Clear Lake township, Hamilton county, Early, Sac county, and scarlet fever at Woodbine, Harrison county, and at Dubuque Speaking of the epidemic at Dubuque, the *Globe Journal*, of that city says "Scarlet fever and diphtheria are spreading to an alarming extent in Dubuque Four cases were reported this morning by Sanitary Officer Starr to the city health physician and cards tacked upon the infected houses These diseases are confined to children between the ages of 5 and 16 years and are becoming so prevalent that the question of dismissing the schools is being seriously considered There is a great deal of complaint about people who remove cards from their houses before the time provided by the ordinance The latter provides that a card placed on an infected house shall not be removed for thirty days A case was reported to the sanitary officer a day or two since where a lady tore a card down from her house that ought not to have been removed until the 18th of this month and another case was reported where a policeman without any authority whatever removed a card Under the ordinance these persons are liable to arrest and prosecution and they have no more right to remove a card and go unpunished than have the most humble individual in the city The board of health should order that the cards be replaced When a card is removed people suppose that there is no further liability to catching the disease placarded, and it can therefore be readily seen what danger children are exposed to who happen to visit such houses or play with the children who have had the disease It is said that in some cases physicians attending children afflicted with diphtheria and scarlet fever told their parents that it was not necessary to keep the cards out after the children were up again This is a matter that the public is deeply interested in and the health officer and the board of health will be held reponsible for the strict enforcement of the ordinance The parties who have removed the cards should be compelled to put them up again and comply with the law If this is not done, others may contract the disease There are now about seventy cases of the two diseases in this city"

Health Report of New York State for August, 1896—The *Bulletin* of the State Board of Health of New York, publishes the following summary of the deaths, and rates of deaths by principal causes, for August During August was exprienced the disastrous hot wave beginning on the 6th of the month and continuing ten days, and causing an almost unprecedented mortality among adult males, the aged and the infirm The actual and proportional mortality among children under five years were decidedly lower than in July

The marked deviation from the ordinary mortality of the month, during which there have been reported 12,475 deaths, which is 1,600 more than in the corresponding month of last year, is attributable mainly to deaths from the direct effects of heat (sun stroke), occurring mostly during the early part of the month, 1,125 deaths from this cause having been reported, 1,040 were reported from New York city and Brooklyn, the recorded deaths occurring mostly in the maritime and Hudson valley districts These are reported under deaths from accident and violence There is also, compared with August, 1895, an increase in the reported mortality from diseases of the urinary, nervous and circulatory systems, and also in deaths from old age and from unclassified causes There was no material variation in the mortality from zymotic diseases and consumption, the number of deaths from diarrheal diseases being about the same as last year The death rate was 23 25 against 20 40 in August, 1895 Compared with the preceding month there was a daily average mortality of 402 against 408 in July, the zymotic mortality was less by 750 deaths, the decrease being in the deaths from diarrheal diseases from which there were 2,326 deaths, or nearly 19 per cent of the total, a large number are reported from dysentery, affecting adults There was also a decrease in the mortality from diphtheria, from which there were 257 deaths, a smaller number than in any month for the past ten years, August being generally the month of its smallest prevalence Scarlet fever has almost disappeared from the reported causes of death, but 15 deaths being reported from the maritime district and 4 from the rest of the State Whooping cough increased to 119 death[illegible] uniformly more deaths occur from this cause in August th[illegible] in any other month, the average for the past ten years b[illegible] 125 against an average of 90 for the other months of the [illegible] There is the customary increase in deaths from typhoid [illegible] which caused 171 deaths, the average for the mo[illegible] deaths from local diseases, the only material vari[illegible] those of the digestive system, from which there we[illegible] than in July From the cause stated the reported [illegible] from accidents and violence is largely increased [illegible] mean temperature of the month was 1 degree ab[illegible] mal, but during the first half there was a [illegible] longed period of excessive heat, the mean hi[illegible] was 92 degrees, while the mean lowest [illegible] there was a mean relative humidity of 72 [illegible] eastern part of the State of 78 per cent There was an unusual number of cloudless days, the mean barometer was 30 02, and the rain fall generally deficient

New French Sanitarium for Tuberculous Children at Saint Trojan —The President of the Republic recently inaugurated this new institution on the southwest seacoast (Ile d'Oleron), erected at an expense of about $120,000 to the state, under the superintendence of Dr Bergeron, perpetual secretary of the Académie de Médecine Its official purpose is to hospitalize scrofulous children for tuberculosis The drinking water is sterilized by the new Desmaroux system, at an expense of five centimes the cubic meter, and according to experts in bacteriology, "realizes the last word" in sterilization —*Prog Méd* , September 28

An Island Sanitarium —According to the '*Tiser*, one of the islands in Boston Bay is to be made a summer sanitarium for sick children, and steps are to be taken immediately to carry out the plan Dr W G Macdonald, the city physician, is credited with the origin of the plan, and it is said that the City Board of Health and the mayor actively favor it It is proposed to take the small island, just beyond the iron pier at Marine Park, South Boston It is 160 feet in diameter and unused at the present time, although it is under the jurisdiction of the park commissioners It is contemplated to erect tents and place a milk plant in operation The doctors and nurses will probably be furnished from the City Hospital The location selected is a most desirable one for many reasons The island can be reached from any section of the city by electric cars to City Point during the day or evening There will be an out door and in door patients' department, and the chances of saving a baby's life will be much better on the island than at the home About a week ago Dr Macdonald called upon Mayor Quincy and unfolded the scheme, which was favorably received by his honor, after learning the facts and figures The large number of deaths during the two months was astonishing to him Dr Macdonald wrote to Conrad Reuter, Secretary of the Boston City Hospital trustees, in relation to the matter, and they will consider the scheme at their next meeting The letter follows

"For some time past I have been considering the question of infant mortality in Boston during the summer months, and I have been more and more impressed with the idea that our present means of care and treatment of the little ones are inadequate During July and August of the current year, there were reported to the Boston Board of Health 2,438 deaths from all causes, and including all ages Of these 919 were infants less than 1 year old Four hundred and ninety two were classed under the head of 'cholera infantum ' If we add to this 492, those which were classified as 'enteritis,' 'gastro enteritis,' 'diarrhea,' etc , we will have a total of nearly six hundred and fifty deaths directly attributable to the weather conditions of these months Thus we see that during the heated term more than a third of the total deaths occurred in infants under 1 year, and more than a fourth were due to preventable causes These figures have a pathetic eloquence of their own We have at the present time two noble charities engaged particularly in the care of the suffering babies I mean the floating hospital and the Hospital at Rainsford's Island Both were inaugurated as private charities although one has become a public charge since No improvements could be made on the methods of treatment now in vogue in these two institutions, since one is under most careful and intelligent management and the other is under the directorship of Dr T M Rotch, a gentleman who has no superior in the treatment of infantile ailments Both, however, have the same disadvantage in caring for acute cases, in that boat service is an integral part of both systems Boat service means a fixed time for reception, and if that time be exceeded there is a delay of twenty four to forty eight hours Every physician knows that a delay of even minutes may mean the life of the infant Therefore, it seemed to me that if we could procure a site for an infant's summer hospital, which would combine the benefits of the salt water breezes with accessibility at all times, we would be able to reach a large number of cases which are not now treated We would then not supersede but powerfully assist the work now going on, in the directions which I have specified

"Such a site does exist in the artificial island at the end of the iron pier at the Marine Park, City Point We have there a pier extending into the bay for a distance of 2,640 feet, and leading out from a park which is itself almost surrounded by salt water Beyond the end of the pier an artificial island has been built, which is yet unused, and which will be unused for some time This island is about 160 feet in diameter, a space ample for our purpose Having consulted with the secretary of the park commission on the matter I am satisfied that there would be no trouble in securing this place It is ideally situated, and remains cool during the hottest days in summer In using this island for hospital purposes, we encroach on no one's rights, since it has been hitherto unused As it is intended for use only during the summer months, a tent hospital would be all sufficient and Mr Matthew Sullivan, chief of the architect division of the city of Boston, assures me that a few marquees at this place would not detract from the architectural beauties of the park, but would really add to the general effect by giving the whole place a holiday aspect Such a hospital would be extremely inexpensive Its first cost would include simply a few tents and some carpentering No solid buildings and no costly furnishings would be needed Then would come the question of supplies, and the assistants, who perhaps could be transferred from the central hospital As to the management of such an institution I see no way in which it could be done so thoroughly, so scientifically and so economically as through your boards Your physicians, nurses and attendants have had experience in tent work, and you have already a completeness of organization which could only be effected by any other body at the expense of much time and labor Besides, the poorer people are acquainted with your work and have confidence in it Mothers would thus be willing to intrust their babies to your care Physicians, too, understand the routine by which a patient may be admitted to the Boston City Hospital, and I am satisfied that they would be extremely pleased to have a station to which they might send their infant charges with as little trouble as is now necessary to secure hospital treatment for adults This communication is sent to you at the suggestion of his honor, Mayor Quincy, with whom I have conferred on the matter "

The trustees will hold a meeting in a short time, and it is expected that they will do all in their power to make the scheme a success

BOOK NOTICES

A Text book for Training Schools for Nurses, including physiology and hygiene and the principles and practice of nursing By P M Wise, M D With an introduction by Dr Edward Cowles In two volumes Vol I New York and London G P Putnam's Sons, 1896

The purpose of the book as stated by the author is "to provide a text-book that will suffice for all the recitations in a two years' course in training schools for nurses " 'The course adopted" in these volumes, says the author, "is based upon the hypothesis that a nurse must understand the fundamental principles of physiology and hygiene before a rational understanding of the principles of nursing is possible " The first volume is therefore preparatory, being intended for the first course, and the second volume for the principles and practice of nursing The book is dedicated to that veteran hygienist and superintendent, Dr Edward Cowles

A System of Surgery, by various authors Edited by Frederick Treves, F R C S Vol II, with two colored plates and 487 illustrations 8vo, cl , pp 1120 Philadelphia Lea Brothers & Co , 1896

This volume concludes the work, and will add very considerably to the surgical literature of the period It includes "Injuries and Diseases of Muscles and Tendons," by W Arbuthnot Lane , "Surgery of Deformities," by H H Clutton , "Injuries and Diseases of the Head," by H P Dean , "Injuries and Diseases of the Spine," by W H Bennett , "Concussion of the Spine," by H W Page , "Diseases and Injuries of the Ear," "Diseases of the Nose," by A Marmaduke Sheild , "Injuries and Diseases of the Neck," by Bernard Pitts , "Surgery of the Chest," by Pearce Gould , "Affections of the Mouth, Palate, Tongue, Tonsil and Pharynx," by H F Waterhouse , "Affections of the Esophagus," by W Bruce

Clarke, "Injuries and Diseases of the Abdomen," and "Hernia," by F Treves, "Diseases of the Rectum," by Charles B Ball, "Diseases of the Breast," by W Watson Cheyne, "Injuries and Diseases of the Urinary Organs," "Injuries and Diseases of Testes, Scrotum and Penis," by Henry Morris, and "Injuries and Diseases of the Female Genital Organs," by J Bland Sutton The illustrations are copious but not very well worked out owing to the thin paper Many of them are original This system is an excellent exponent of *fin de siecle* British surgery

Medical and Dental Colleges of the West HISTORIC AND BIOGRAPHIC, Illustrated in photogravure and steel Edited by H G CUTLER Full gilt, quarto, pp 639 Chicago Oxford Publishing Company, 1896

This is the Chicago volume and only one published of a series in which the other western cities are to take their turn So far as we can judge the work has been committed to trustworthy hands The history of Rush Medical College was written by Prof Norman Bridge and Dr John Edwin Rhodes, the Northwestern Medical College by Prof S J Jones, the Woman's Medical School by Prof Marie J Mergler, the College of Physicians and Surgeons by Profs D A K Steele and William E Quine, the Chicago College of Dental Surgery by Prof Truman W Brophy, the Northwestern University Dental School by Prof Edgar D Swain, the Chicago Policlinic by Prof Truman W Miller, the Post Graduate Medical School by Prof W Franklin Coleman, Harvey Medical College by Prof Frances Dickinson, and other schools sectarian in character by those of their own sect In addition to the school histories, biographies of those connected with the several schools are given and in many instances of prominent alumni The work is handsomely printed on fine paper and bound in morocco As an authoritative work on the subject it is not likely to be superseded for many years to come

Anatomy, Descriptive and Surgical By HENRY GRAY, F R S A new edition, thoroughly revised by American authorities, from the thirteenth English edition Edited by T PICKERING PICK, F R C S, with 772 illustrations, many of which are new Pp 1250 Philadelphia and New York, Lea Brothers & Co 1896

When a book reaches its thirteenth edition and has become a standard authority in two hemispheres, there is little to say by way of review

We can only congratulate the editor on the new edition, the publisher for the munificent way in which he has supplied the fine paper, the beautiful illustrations and the superb binding

The new American edition, however, is something more Certain sections have been rewritten, viz, those on the brain, the teeth and the abdominal viscera Dr B B Gallaudet, Dr Fred J Brockaway and Prof J Playfair McMurrich have had charge of the American revision

The Medical and Surgical Uses of Electricity By A D ROCKWELL A M, M D Illustrated with two hundred engravings New edition New York William Wood & Co

No praise could be too high to give this standard book, which is essentially the ninth edition of the well known "Beard and Rockwell" The work has been brought down to date, as one may easily satisfy himself by examining the chapter on electro surgery, which has included the Roentgen ray and the directions for its use "Rockwell" will be turned to as a book which has not disappointed its possessor

A Manual of Pharmacology and Therapeutics By WILLIAM MURRELL, M D, F R C P, Physician to and Lecturer on Pharmacology at the Westminster Hospital, late Examiner in Materia Medica in the University of Edinburgh, and Examiner in Materia Medica and Pharmacy to the Conjoint Board of the Royal College of Surgeons of England, and the Royal College of Physicians of London New York William Wood & Co 516 pages

The friends of Dr Murrell in this country, and they are many, will be extremely glad to welcome this book, which, although not exhaustive, is yet eminently scientific and practical The American edition has been revised by Dr Frederick Caswell of New York The book includes a very entertaining introduction, in which the general principles are given Pharmacology of Organic Substances, Pharmacology of Synthetic Compounds, Pharmacology of Drugs of Vegetable Origin, Pharmacology of Drugs of Animal Origin

Annual Report of the Board of Health and the City and Port of Philadelphia for the year 1895

The volume is included in a city document containing the first annual message of Mayor Warwick, and the Director of the Department of Public Safety The Board reports that the death rate, while slightly in excess of 1894, was rather better than the average for the last ten years, being but 20 44 per 1,000 In regard to antitoxin in diphtheria the Board says "Antitoxin as an immunizing agent has been used so very sparingly that its influence in restricting the disease has not been appreciable Its use as a curative means has been considerable but far from universal, and while its efficacy may *have been demonstrated in many cases, its use has been* too limited as yet to exercise a marked limiting effect upon the disease" A laboratory of bacteriology was established at a cost of $15,000 The report shows a vast amount of excellent sanitary work during the period covered by the report

The Juggernaut of the Moderns, A novel By ROSA HUDSPETH The Arena Publishing Company, Boston, Mass 1896 Price 50 cents

This book is one that has no place in the modern household, nor should it be placed in the hands of the miscellaneous reader Those interested in sociology will find the book entertaining The story is of the ruin of a young woman who goes to a Western town as a typewriter She is is pictured by the authoress as of surpassing beauty, of course, but owing to the fact that she must wear a corset, and displace the abdominal organs, is subject to attacks of hysteria Such a condition naturally makes the subject a fit victim for the wiles of the hypnotist, and her struggles against the dominant influence, and final overthrow, form the materials for the book *Cui bono?*

Kemp & Co's Prescribers' Pharmacopeia A synopsis of the more recent remedies, official and unofficial, with a therapeutic index Third edition Bombay Kemp & Co, Ld 1896

We have tested this book for its account of several of the newer remedies and find it quite accurate, so far as our test goes There is no doubt but it will be found useful in many countries beside India, for which it was originally prepared The additions to the last revisions of the British and U S Pharmacopeias are included in this work It appears there has been no revision of the Indian Pharmacopeia since the edition of 1868

The compilation has been well done the arrangement is systematic and convenient.

Transactions of the Forty sixth Annual Meeting of the Illinois State Medical Society, held in Ottawa, Ill, May 19, 20 and 21 Chicago, 1896

This volume is characterized by its directness throughout The transactions are singularly free from superfluous verbiage, and the authors, as a rule, plunge *in medias res* without any circumlocution The tendency of the time is shown by the appearance of a Committee on Society History, which, a foot note informs us, is composed of those members who have held continuous membership for forty years Although several of the papers have been printed in this JOURNAL many of them have not been elsewhere printed The Society will next year meet at East St Louis and the Missouri State Medical Society will meet at St Louis at the same time We notice that a joint committee has been appointed to act [illegible] mittee from the Missouri State Society [illegible] for one day's joint meeting

An American Text book of Applied Therapeutics for the Use of Practitioners and Students Edited by J C Wilson, M D, Philadelphia, assisted by Augustus A Eshner, M D, Philadelphia The authors are I E Atkinson, Baltimore, Sanger Brown, Chicago, John B Chapin, Philadelphia, Wm C Dabney, Charlottesville, Va (deceased), John C Da Costa, Philadelphia, I N Danforth, Chicago, John L Dawson, Charleston, S C, F X Dercum, Philadelphia, George Dock, Ann Arbor, Robert T Edes, Boston, Augustus A Eshner, Philadelphia, J T Eskridge, Denver, F Forchheimer, Cincinnati, Carl Frese, Philadelphia, Edwin E Graham, Philadelphia, John Guitéras, Philadelphia, Frederick P Henry, Philadelphia, Guy Hinsdale, Philadelphia, Orville Horwitz, Philadelphia, W W Johnston, Washington, D C, Ernest Laplace, Philadelphia, A Laveran, Paris, France, James Hendrie Lloyd, Philadelphia, John Noland Mackenzie, Baltimore, A Lawrence Mason, Boston, Charles K Mills, Philadelphia, John K Mitchell, Philadelphia, W P Northrup, New York City, William Osler, Baltimore, Frederick A Packard, Philadelphia, Theophilus Parvin, Philadelphia, Beaven Rake, London, England, E O Shakespeare, Philadelphia, Wharton Sinkler, Philadelphia, Louis Starr, Philadelphia, Henry W Stelwagon, Philadelphia, James Stewart, Montreal, Charles G Stockton, Buffalo, James Tyson, Philadelphia, Victor C Vaughan, Ann Arbor, James T Whittaker, Cincinnati, J C Wilson, Philadelphia Price, cloth, $7, sheep, $8 Philadelphia W B Saunders

This is a book about the same size as the text book on surgery, and the others of the American text book series

We note with pleasure that the metric system of dosage has been applied throughout, in addition to the old apothecary doses for those who do not care to employ the modern form We regret to see that in the article on actinomycosis, the author has failed to notice the work of the Agricultural Department of our Government in this matter, and we believe that the use of potassium iodid was first promulgated by this bureau, and that the foreign authors are not entitled to priority in the matter We trust that Dr Salmon will be a little more liberal in the distribution of the valuable documents of the Department of Agriculture, Bureau of Animal Industry, they may in time reach the book writers

The Tonic Treatment of Syphilis By E L Keyes, A M, M D Revised edition, 8vo, cl, pp 78 New York D Appleton & Co 1896

The author holds in this essay that "mercury in small doses is a tonic, because under it the general vitality is improved and the number of red blood cells increased"

Twenty years have passed since Professor Keyes gave his views on this subject, and we think he has a right to claim that his position has been fully sustained, and to him more than to any other one man has been due the disappearance of professional prejudice against the use of mercury, in many forms of the disease

The Transactions of the State Medical Society of Wisconsin, for the year 1896, with the Constitution and By laws and list of members Cloth, 8vo, pp 593 Madison, Wis Tracy, Gibbs & Co 1896

This meeting of the Society being the semi centennial anniversary of its foundation it was decided to make it of a popular character and of direct benefit to the people All papers therefore were upon hygienic topics The volume thus produced is a very creditable one and shows a high state of learning in the principles of sanitary science by the Wisconsin faculty We doubt if there are many States in our Union where current topics in hygiene would have received as intelligent treatment The volume concludes with the obituaries of deceased members and the statistics of local societies Secretary Sheldon has edited the volume with his usual skill and precision The next annual meeting will be held at Racine on the first Wednesday in May, 1897

Transactions of the Medical Society of the State of Pennsylvania at its forty sixth annual session, held at Harrisburg, 1896 Vol XXVII Published by the Society, Philadelphia, 1896

Beside the usual number of valuable medical and surgical papers in this volume there is a very interesting summary of the proceedings of the Society from its original meeting by Permanent Secretary William B Atkinson The volume is well arranged and has an excellent index Pittsburg was selected as the next place of meeting The minutes are very full and show the active interest taken in various matters other than pure medical science by the Pennsylvania brethren This society sets a good example to sister societies by devoting a page in its Transactions to the American Medical Association, explaining the method of obtaining membership and giving a favorable notice to the Journal

Feeding in Early Infancy By Arthur V Meigs, M D Octavo, flexible cloth, pp 15 Price 25 cents Philadelphia W B Saunders 1896

This essay was one read at the meeting of the Philadelphia County Medical Society, April, 1896 The article discusses the composition of milk, and gives methods of imitating human milk by proper treatment of cow's milk

Practical Points in Nursing for Nurses in Private Practice, with an appendix, etc, by Emily A M Stoney, etc, pp 456 Philadelphia W B Saunders 1896 Price $1 75 net

In this book the author has rather successfully covered the topics of the entire range of private nursing, and how to meet the various emergencies when distant from medical aid, convenient tables, a dose list in old apothecaries' weights, and a glossary conclude this excellent volume

A Manual of Obstetrics By W A Newman Dorland, A M, M D, with 168 illustrations in the text and 6 full page plates Philadelphia W B Saunders 1896 Price $2.50 net

This is a well written text book, containing the essential knowledge of the art The illustrations are numerous and clear, and the work will be found sufficiently comprehensive to meet ordinary wants

Peroxid of Hydrogen (Medicinal) Glycozone, Hydrozone and Eye Balsam By Charles Marchand Treatment of diseases caused by germs, bacteria and microbes Eleventh Edition, pp 216, Paper New York, 1896 Sent free on application

This book contains direction for using the above preparations, and a number of articles by medical writers based upon their experiences with these drugs, which have appeared in the various medical journals

ASSOCIATION NEWS

The Rush Monument—The Rush Monument Committee has sent the following circular to the Regular profession, which we hope will be heeded

My Dear Doctor—The remarkable success of the relatively small body of homeopaths in the United States, in collecting $75,000 for their monument to Hahnemann to be erected in the city of Washington, ought to make every reputable regular physician in the country keenly alive to the necessity for promptly subscribing to the fund for the long delayed monument to Benjamin Rush

The model for the monument to Hahnemann, which has been on exhibition in New York city, has attracted general admiration on account of its great beauty and artistic excellence, which will make it unrivaled as a work of this kind

The regular medical profession, numbering over one hundred thousand more than the entire body of homeopaths, has thus far subscribed less than $4,000 toward the projected monument to Dr Rush, for which the Navy Department has already generously designated a commanding site in the park fronting the U S Naval Museum of Hygiene, where it will be one of the most conspicuous features of the National capital

Are the regular physicians of the United States willing that this illustrious signer of the Declaration of Independence and the distinguished medical hero of the Revolution, shall be commemorated by an insignificant bust or a mediocre statue, in pitiable contrast with the splendid testimonial at their capital city to a foreign theorist by a comparatively small body of his misguided followers? The crowds of visitors to Washington can not fail to attach a disparaging significance to the spectacle of these two monuments, and we appeal to you to aid the Committee in its endeavor to do justice to the memory of this great father of American medicine pure and undefiled, by sending *by return mail* to either of the undersigned as large a contribution as you may be able to make

ALBERT L GIHON, M D ,
Chairman, R M C , 8 W 127th Street, New York City
GEORGE H ROHE, M D , Sec and Treas , R M C , Sykesville, Md
W MURRAY WEIDMAN, M D , Chairman of R M C for Pennsylvania, Reading, Pa
HENRY D HOLTON, M D , Treas Am Public Health Association, Brattleboro, Vermont
CHARLES McINTIRE, M D , Sec and Treas , Am Academy of Medicine, Easton, Pa

PRACTICAL NOTES

Artificial Respiration for Infants —Laborde's method of artificial respiration by rhythmic traction of the tongue is recommended in the *Cbl f Gynek* No 28, as especially adapted for newborn infants There is none of the painful impression produced on the witnesses by balancing the infant, and it can even be treated while in a warm bath In one case traction repeated forty times recalled the babe to life after 600 oscillations had failed to produce any effect The infant died eight hours later, and numerous cutaneous and subcutaneous lesions were found, evidently caused by the balancing The traction had only caused ecchymosis at the tip of the tongue, in the palatine arch, in the cellular tissue back of the esophagus and in its mucosa These lesions should be known as they might have a medico legal bearing in cases of suspected suffocation—*Bulletin Méd* , September 9

Transverse Resection of Tuberculous Kidney —Bardenheuer, some years ago, proved experimentally the possibility of this operation, and Czerny, Kummell, D'Antona also have affirmed that it could be performed on man Bardenheuer has recently applied it to a couple of patients found on investigation to have the lower part of the kidney affected with tuberculosis He made a transverse section and cut off section after section until absolutely healthy tissue was reached The first case was much enfeebled from traumatic suppuration in the region four months previously, with intermittent fever, and the patient succumbed five hours after resection of the kidney, although the operation had been completed in twenty five minutes, and had been attended with scarcely any loss of blood The other case recovered with no complications For a month urine oozed into the dressing, which was changed every day After this period the wound healed and the patient recovered rapidly The indications for resection in such a case are strict limitation of the lesion to a part of one kidney and no traces of infection in the ureters or small pelvis —*Deutsch Zeitschrift f Chir* No 6

The Surgical Treatment of Focal Epilepsy—From a critical analysis of the results in nineteen cases Drs B Sachs and A G Gerster draw the following conclusions

1 Surgical interference is advisable in those cases of partial epilepsy in which not more than one, or at the utmost two years, have elapsed since the traumatic injury or the beginning of the disease which has given rise to the convulsive seizures

2 In cases of depression or other injury of the skull surgical interference is warranted even though a number of years have elapsed, but the prospect of recovery is brighter the shorter the period of time since the injury

3 Simple trephining may prove sufficient in a number of cases, and particularly in those in which there is an injury to the skull, or in which a cystic condition is the main cause of the epilepsy

4 Excision of cortical tissue is advisable if the epilepsy has lasted but a short time, and if the symptoms point to a strictly circumscribed focus of disease

5 Since such cortical lesions are often of a microscopic character, excision should be practiced even if the tissue appears to be perfectly normal at the time of operation but the greatest caution should be exercised in order to make sure that the proper area is removed

6 Surgical interference for the cure of epilepsy associated with infantile cerebral palsies may be attempted particularly if too long an interval has not elapsed since the beginning of the palsy

7 In cases of epilepsy of long standing, in which there is in all probability a widespread degeneration of the association fibers, every surgical procedure is useless —*Am Jour Med Sciences*, October

Albuminuria in Pregnancy and Parturition and Its Relations to Eclampsia —The *British Medical Journal* quotes Saft, in the *Archiv für Gynäcologie*, as saying that albuminuria occurs during the latter half of gestation in 5 41 per cent of all cases, more frequently toward the end of pregnancy and oftener in primiparæ (5 9 per cent) than in multiparæ (4 1 per cent) it is more common also in the former (32 08 per cent) than in the latter (22 6 per cent) during labor As a rule it disappears within a few days after delivery, but is more likely to persist in primiparæ, in whom the effects of gestation upon the kidneys are altogether much more serious than in multiparæ White and red corpuscles in non albuminous urine of pregnant women come from the bladder, but neither during pregnancy nor labor are cylinders found without albumin, though their presence does not seem to depend on the degree of albuminuria, nor to influence its duration Twins and hydramnion are predisposing factors, contraction of the pelvis also, but in multiparæ only during labor Premature labor is a frequent result There is an affection of the kidney due solely to the condition of pregnancy, the pathologic changes in which are merely degenerative, this affection is quite different from nephritis when not complicated it is of favorable prognosis and not likely to terminate in chronic inflammation, but when accompanied by actual nephritis, or disease of the heart, is of very doubtful issue The cause of this affection is probably the auto intoxication of the system by some product of tissue change, such as is the origin of the molimina graviditatis and of the nervous disturbances of the pregnant state The muscular exertion during labor throws extra work on the kidneys, and it is the overloading of the system by this poisonous product that causes eclampsia and the secondary changes in the kidneys, liver and other organs There is thus an intimate, if not a causal connection between albuminuria and eclampsia, and the only proper way to solve the mystery surrounding the latter is to try to determine the nature of the active poison by observations made during gestation In the same journal Schreiber analyzes a large number of cases that have come under treatment since Schauta s report, June, 1880 Of 42 607 confinement cases 137, equal 0 321 per cent., suffered from eclampsia, 19 being already unconscious and many others having had many fits before being admitted to the clinic Of the mothers 109, 79 5 per cent , were primiparæ 113 (97 1 per c) were not more than 30 years old One only had had eclampsia in a previous (first) confinement (4 para sect Cæs) Twins are noted 12 times, hydrocephalus, hydramnion and low lateral placenta one each abnormal rotation twice abnormal pelvis 9 times, 3 breech cases The attacks commenced before labor in 16 78 per cent , during it in 62 04 per cent , and after delivery in 21 16 per cent of the cases, and while 53 17 per cent had less than 5 fits, the average number of fits in 126 was 8 Omitting the 34 children of 29 postpartum cases, of the remaining 115, 37, equal 32 1 per cent , were stillborn, and 56, equal 48 6 per cent , were premature The fetus in 4 antepartum cases was macerated, but the mothers recovered , nor did prolonged duration of the eclamptic state imply a fatal termination The central nervous system was affected in 7 women, 6 had puerperal mania After delivery 62 had no more fits, 5 had only 1, 37 had more than 1, 3 died from Cæsarean section, 29 were puerperal cases In 50 7 per cent of the whole, or 64 7 per cent of the cases before delivery, emptying the uterus had a good effect In 78 cases operated on (5 induction only) the proportion was 62 7 per cent , in 27 delivered spontaneously 70 3 per cent Of 27 deaths (19 7 per cent) 17 only were due to eclampsia alone (12 4 per cent) Four fatal cases only were more than 30 years old, but the mortality of multiparæ (6, equal 21 4 per cent) was greater than that of primiparæ (21, equal 19 2 per cent) The relative mortality of cases commencing before, during, or after childbirth was 30 43 per cent , 18 82 per cent and 13 79 per cent The proportion of deaths is comparatively low, and with the fact shown that delivery without too active interference tends to stop the fits is sufficient to warrant the adoption of conservative treatment for eclampsia, the rather as the woman is spared the dangers inseparable from forced labor The practice of the Vienna clinic for many years has been a prophylactic milk diet for all albuminuric pregnant women if this fail, the induction of labor by bougie or colpeurynter On the outbreak of eclampsia, hot baths, linden tea, wet packing, chloroform and delivery as soon as may be without incisions

NECROLOGY

Elisha Griswold, M D (Jefferson Medical College) at Pittsburgh, October 7 aged 68 He was born in Chester, Pa , March 14, 1828 He was appointed in 1861 by Governor Curtin surgeon of the One Hundred and Twelfth Pennsylvania Volunteers, but afterward became acting division surgeon July 30, 1864, he resigned to accept an appointment by President Lincoln in the corps of United States surgeons Dec 14, 1864, he was transferred to the charge of Judiciary Square Hospital, afterward being sent to New Orleans as chief medical examiner of the Freedmen's bureau for the State of Louisiana In 1867 he was commissioned as lieutenant colonel He was a member of the Mercer County Medical Society, the Trumbull Medical Society of Ohio, and other societies He leaves a wife and two sons

J v Kerchensteiner, M D , Bavaria, aged 65 years The distinguished hygienist and promoter of medical, pharmaceutic and sanitary progress His death is a great loss to his country

John Seibert, M D (University of Pennsylvania, 1857) Chicago, October 9, aged 78 ——George Bonbright Anderson, M D (Jefferson Medical College, Philadelphia, 1877) at Latrobe, Pa , October 5 ——William Eaton, M D , Lloydsville, Ohio, October 6

MISCELLANY

Foundation of Medico surgical Urological Society —This new association recently formed in France, welcomes foreign correspondents, who are requested to apply to Dr Desnos, 31 Rue de Rome, Paris

Inefficient Telephone Service in Columbus —At a recent meeting of the Academy of Medicine of Columbus, Ohio, resolutions were passed reflecting on the telephone service of that town, and a committee was appointed to take proper action in the matter

Pawtucket (R I) Medical Association —The Pawtucket (R I) Medical Association petitioned the city council for the establishment of a modern board of health, without which that city at present languishes

Dr B Mead Bolton, bacteriologist of the Board of Health at Baltimore, Md , has been appointed professor in bacteriology and pathology by the board of curators of the Missouri State University

Chicago Day was observed thoughout the city October 9 The vast processions required medical attention and the Health Department established stations and furnished ambulance service It is under existing ordinances clearly the duty of the city physician to attend to the service of this character, but no appropritions have been given the city physician for these purposes

Dean of the Profession —Since the death of Dr Salomon of England, at the age of 106, Dr Bossy of Havre, France, is now, we believe, the dean of the profession Dr Salomon retired at an early age after his marriage to an heiress, but Dr Bossy has practiced all his life

Robbed Doctors' Houses —Two female sneak thieves were arrested in Chicago, October 5, charged with stealing articles from doctors' offices which they had visited under various pretences About fourteen physicians have sustained losses at the hands of this precious pair Umbrellas, vases, clocks and the like were classes of articles taken

American Methods of Treating Pelvic Suppurations —As a supplement to the discussion of this subject at the International Gynecological Congress, the *Bulletin Médical* summarizes the views of several of our American surgeons Noble, Kelly, McMurtry, Sutton, Stone, Cordier, Marcy, F H Martin, Treves, Wiggin, Kelsey and Carpenter, Ashby and Penrose, quoting extensively from the addresses and discussions at the Atlanta Meeting, published in The Journal, Nos 4 to 6 As has been seen in the report, Byford, Henrotin, Edebohls, Polk and Kelly took an active and important part in the proceedings

Form of "Charcot's Crystals "—New light has been thrown on this subject by Cohn's recent investigations He has found that they are not quadratic octahedrons as supposed, but hexagonal double pyramids The cleavage of the figures found in dried asthma sputum distinctly revealed that they belonged to the hexagonal system Crystallographic tests also proved essential differences between these crystals and Bottcher's, whose plane of polarization is not parallel to the long axis of the crystal —*Deutsch Med Woch* 19, from *Deutsch Archiv f k Medicin*, 4 and 5

Can Not Interfere with Proceedings in Higher Tribunals —The supreme court of Georgia holds, in the case of Baughn v Wiley, decided April 27, 1896, that proceedings to obtain a commission de lunatico inquirendo, under Section 1,855 of the Code of that State, for the purpose of having a person imprisoned in the jail of a given county sent to the asylum as a lunatic, can not be maintained when it appears that such person has been convicted of murder in another county, is subject to the sentence of death, and was confined in the jail in question under an order of the superior court in which the conviction was had and that in such case the writ of mandamus will not lie to compel the ordinary of the county in the jail of which the alleged lunatic is confined to entertain jurisdiction of such proceedings

Methylene Green for Staining Nerve Terminals in the Muscles —Corominos in the *Revista de Ciencias Medicas de Barcelona*, 3, states that this substance stains the terminal ramifications of the axis cylinders much better than the blue or chlorid of gold He uses it in a solution of 100 parts of concentrated aqueous solution of methylene green in 50 parts of absolute alcohol and 1 part acetic acid He leaves the sections twenty-four hours in this solution, and then makes his preparation with glycerin and salt solution The nerve fibers take a fine green while the muscle fibers remain a very light color If left too long the preparation can be decolorized by soaking a while in salt free glycerin

Philadelphia Municipal Home for Consumptives Proposed —Dr Lawrence F Flick, President of the Society for the Prevention of Tuberculosis of Philadelphia, has proposed to the city that some suitable spot for a consumptives' home be selected, whereby those cases to be cared for by themselves in a sanitary way and those already cared for by the municipality, shall be gathered in one institution to be managed under municipal regulation The plan is said to meet with favor by the municipal authorities It is evident that additional means must be taken to prevent the spread of the disease This seems practical and, managed under proper conditions, would be an enormous factor in suppressing the disease in a large city

Essential of Indictment for Attempting to Procure Abortion —A Vermont statute renders all acts done and performed upon a woman pregnant, or supposed to be pregnant, with intent to procure her miscarriage, criminal, unless the same be necessary to preserve her life R L, sec 4247 Construing it, the supreme court of the State holds, in the case of State v Stevenson, decided Aug 21, 1896, that "the same" here refers to the miscarriage, and not to the means to produce a miscarriage, as it can not be said that the thrusting of an instrument into a pregnant woman, who is otherwise in perfect health, is necessary to preserve her life, or that the employment of any of the means commonly used to procure a miscarriage is necessary to preserve her life Under the statute, if a miscarriage is necessary to preserve the life of a pregnant woman, all acts done with the intent to procure it are declared lawful, but, if unnecessary, criminal In order to charge an offense under the statute, it is necessary to negative the exception And the court further holds that an averment that the means employed to procure the miscarriage were not necessary to preserve the life of the woman is not an equivalent to an averment that the miscarriage was not necessary to preserve her life, and that it does not negative the exception

False Testimony and Suggestion —Bérillon found by recent experiments that he was able to secure the testimony in regard to imaginary past occurrences, of over twenty out of every hundred persons tested (all over 15), by verbal suggestion alone, and without any preliminary hypnotic maneuvers The readiness with which he was able to accomplish this was in direct relation to the intelligence of the subject, by no means confined to the lesser developed, but the reverse He also found that a personal interest assisted the realization of the occurrence, for instance, the subject remained indifferent to a suggested criminal occurrence until he was made to believe that the person in question had spoken injuriously of him, when his attention was at once aroused and the whole imaginary occurrence impressed upon his memory as if he had actually witnessed it Bérillon states therefore that large numbers of persons possess such suggestibility in the normal condition that it would be easy by verbal suggestion alone, without any hypnotic maneuvers, to cause them to commit unconscious perjury, and that they should not be considered legally responsible if psychologic examination by a medico legal expert establishes the fact of the suggestion Magistrates are therefore warned against the possibility of suggesting false testimony to impressionable witnesses by the questions asked and methods of procedure, which may produce the same effects by psychic constraint as the torture chambers of old See *Journal de Méd de Paris* for further particulars, September 27

Inebriety, Insanity and Suicide —Inebriety, though long continued and resulting occasionally in temporary insanity, the prerogative court of New Jersey holds, in Koegel v Egner, decided Aug 17, 1896, does not require proof of lucid intervals to give validity to the acts of the drunkard, as is required where general insanity is proved Consequently where habitual intoxication is shown there will be no presumption that incapacitating drunkenness existed, for example, at the time of making a will And if it be conceded that bona fide attempts to commit suicide and accomplishment of suicide, this court further holds it will not follow that such derangement is inconsistent with the ability to make a will It may exist with testamentary capacity The court says that we generally attribute the act of self destruction to a morbid condition of the mind, which may be either fixed insanity or a temporary surrender of reason It is regarded as being in the latter condition where the object of the intended suicide is to secure relief from present pains, either in realization of affliction (mental or physical), disgrace or disaster, or the impelling cause is the apprehension of such evils, for we can not believe that a mind can be in normal health, even though it be cowardly and skeptic as to the future, if it accepts the uncertainty of the state after death as a relief from present mental or physical suffering Proof of mere attempt at suicide and suicide, without more, exhibit at best but a temporary mental affliction, having no reference to antecedent or subsequent periods of time

•

The Monument of Paracelsus —In a chapel in Salzburg, Bavaria, stands Paracelsus's monument It is a broken pyramid, and a niche contains his picture with a Latin inscription commemorating his skill as universal It also sets forth that he has cured diseases before considered as past help, and the he had left his property to the poor His coat of arms is engraved on the monument, with the motto *Pax vivis requies æterna sepultis*, peace to the living, the repose of eternity to those who slumber Perhaps one of the most brilliant minds of the later centuries was Philipp Theophrastus von Hohenheim, or, as he afterward named himself, Paracelsus His parents were persons of note, the father was a physician of acknowledged ability and the mother the superintendent of the hospital at the Abbey of Maria Einsiedeln At this place their child was born in 1493 He grew up in the mountain region and his early instruction received diligent attention He learned the medical art from his father, then at 16 he became a student at the university of Basel, but soon left to be a pupil of the distinguished alchemist and philosopher, Trittheim bishop of Wurzbrug He afterward spent a season at the laboratory of Sigismund Fugger, in the Tyrol, then, after the example of the sages of ancient times, he made a tour of the various countries It is affirmed that he went to Tartary, India and Constantinople He was a persistent seeker after knowledge, accepting it with equal readiness from the learned and from persons in the humbler walks of life He held the learning of the universities in low esteem and despised those scholastic discussions which turn more on theories and definitions than on actual knowledge The skill of Paracelsus as a physician was highly esteemed He was for some time a surgeon in the imperial army, and when he had taken up his residence at Basel he was consulted by Erasmus At the recommendation of Œkolampadius, the Protestant reformer he was made city physician and appointed professor of medicine at the university It was no easy task that he set himself, the reformation of the art of healing Luther in Germany, and Zwingli in Switzerland, had no harder task He delivered his lectures in German instead of Latin, and taught new doctrines in medicine and philosophy This created implacable hostility [illegible] his professional rivals, who accused him [illegible] medical degree He would not prescribe drugs sold by the apothecaries and they joined in the attack He was compelled to leave Basel and led a roving life for several years At length Duke Ernst of Bavaria, who was a lover of occult knowledge, gave him a home at Salzburg But the unrelenting hatred of his enemies pursued him to this retreat, and he was treacherously murdered in September, 1541 —Dr Alexander Wilder, in *Metaphysical Magazine*, September

Equity Will Protect Incapacitated Persons —It seems to be the general consensus of judicial opinion, says the court of civil appeals of Texas, in the case of Edwards v Edwards, where a rehearing was denied September 18, 1896, that equity jurisdiction is maintainable on the petition of a "next friend," in cases where a person of weak mind has not been, or can not be, adjudged a lunatic by the special tribunal provided by law for that purpose, and yet is so far incapacitated by disease, decrepitude, or other infirmity, as to require the protection of a court of equity against the undue influence and fraud of others

Medical Department Syracuse University —The formal opening of the new medical college building took place at Syracuse October 5 About four hundred guests were present, and they were received in the lobby on the first floor by Chancellor and Mrs Day Dr and Mrs H D Didama, Dr and Mrs Nathan Jacobson, Dr and Mrs Alfred Mercer, Dr and Mrs John Van Duyn, Dr and Mrs H B Allen, Dr and Mrs A B Miller, and Dr and Mrs H B Elsner In part Chancellor Day said

> I feel that we have great reason for congratulation to night, reason to congratulate the city of Syracuse Some of our citizens may consider us a burden, but were they to understand the merits of the university they would be with us in congratulating Syracuse that she has the university The university is expending $1,000 per day in Syracuse every day in the week and of a year of 400 days Have you any other institution in Syracuse that pays as good a dividend as that? Not even the street railway I measure the influence more that comes from cultured brains The city has been elevated in character by this institution The university is contributing many sciences to the city and outlying country To night we open a new era Now we have the best appointed medical college on this continent We have made it solid and substantial We have combined things which they have in the metropolis and some things which they had not thought of, and now we have a fine college with a peerless faculty The college ranks with the best to be found We are determined to make doctors We want quality and not quantity There are doctors everywhere, but the doctors you and I want are not so much in evidence I ask that the faculty make as good doctors as they are themselves I introduce to you Dean Didama with profound pleasure

Dean Didama came forward amid applause and made a brief response to the Chancellor's remarks In part he said

> Years ago the Geneva College moved to this city and reorganized as the Syracuse Medical College The system at first in vogue sent out scores of doctors who were not capable to practice A new system was soon adopted and this drove away many who desired to get a diploma rather than to deserve one The new plan was a financial failure Success followed later, however, and now we have facilities for doing work in six departments with the best methods and can furnish a four years' course

The Dean gave a brief review of the faculty and spoke of the high standard of instruction which has been attained Dr D M Totman read the following telegram received by Chancellor Day from Andrew V V Raymond, president of Union University "The medical department of Union University sends greeting and congratulation to the College of Medicine of Syracuse on this happy occasion " Another was read by the Doctor from Anson J Upson, chancellor of the University of New York Letters of greeting were sent by a number of prominent New York physicians

Dr Gaylord P Clark of the faculty gave an interesting history of the new building Dr Clark reviewed the building from its start up to the time of completion The structure cost $65,000 and two thirds of that amount has been raised and was acknowledged in Dr Clark's report The building committee was composed of Hendrick Holden, J B Brooks and J B Clark The old building was torn down early in the summer of 1895, and the present structure was started in July and finished about a fortnight ago The building is four stories high and has a floor space of 24,000 square feet It is spacious, well lighted and well equipped It is heated by steam and the "direct-indirect" method is used for the heating and ventilating It is lighted by both gas and electric lights There are several large lecture halls on the first and second floors On the third floor are the departments of physiology and histology, and on the fourth, anatomy and pathology The floors are all of hard wood and the ceilings steel The side walls are of brick and there is little chance for germs to accumulate It is a modern building and was inspected with pleasure by the large number present last evening

The address of the evening was made by Dr Stephen Smith of New York, a former resident of the county Dr Smith was introduced by Dean Didama, and during his address he gave a review of the various systems of treating the sick, and contrasted the methods of years ago with those of the present time "Natural talent is necessary in order to study medicine," said Dr Smith "The growth of medical schools in this country has not been entirely healthy There is now some advance in sciences, and it is gratifying to note this fact This college was the first to adopt a graded course, and now places itself in the front rank of medical colleges The new building is well equipped, and the school enters now upon a new era The school will of course suffer some competition The best equipped physicians I find are educated in the smaller schools and simply complete their studies in a metropolitan institution The college is to be congratulated upon having secured everything necessary to insure its future success This school furnishes pupils ample opportunity to secure a thorough medical education " Dr Smith's remarks were cordially received Dr Smith has enriched the library by the gift of his large private collection

Hospitals

St Luke's Hospital, New York —When the authorities of St Luke's Hospital sold the hospital lands at Fifth Avenue and Fifty fourth Street, they evidently were not aware that their title only conveyed the property for the use and purpose of a hospital and chapel The matter has now come up in the shape of an unpleasant litigation

Baptist Hospital of Chicago —By the will of the late Mrs Maria M Foster the sum of $35,000 is bequeathed to this institution, which we believe has been up to this time, wholly if not exclusively under the management of the medical sect known as "homeopaths "

ADDRESS

THE EVOLUTION OF MEDICINE AND NEW METHODS OF MEDICAL TEACHING

An address delivered at the ninth annual opening of the Department of Medicine University of Minnesota

BY R O BEARD, M D
PROFESSOR OF PHYSIOLOGY DEPARTMENT OF MEDICINE UNIVERSITY OF MINNESOTA MINNEAPOLIS

The time was, and but recently, when the history of medicine was regarded as the classic introduction to a text book upon medical practice It was the subject of a regular course of lectures in many institutions of medical learning and, in some, it was even assigned to the guardianship of a distinct chair With the rapid growth of the medical sciences and with the multiplication of essential branches of instruction, it has been crowded out of the curriculum Whether wisely or unwisely, in but a very few schools is its study still maintained

This is a loss certainly, and one to be deplored, if the student of medicine does not acquire that loving reverence for his calling which will lead him to investigate its past, if he has not sufficient taste for the literature of his profession to win him to make its history a voluntary part of his education

For this history of medicine—a curious and entertaining story, centering itself in three great facts of character—the passion for self-knowledge, the imminence of human need dependent upon self-ignorance, and the sentiment of human devotion in the sight of suffering, this history of medicine is as complete and chromographic a picture of the evolution of intellect as the records of the race afford

Deeply into its attractive pages I can not venture this evening, but I commend their study to your leisure hours as a recreation from the more arduous duties of your college course From this history I desire only to draw sufficient evidence of the fact that the medicine of to day is the still evolving product of an evolutional process through which it has passed and still is passing to the position not merely of an art, but of a true science And, as the first item of this evidence, observe that medicine, in its development, has always been most quickly responsive to the favorable environment of physical integrity It has always languished in the atmosphere of physical degradation The worship of the body has been an inspiration to the study of its conditions The stalwart races have been the leaders in medical lore The Arabs, the Greeks, the Moors, the Magyars, the Anglo-Saxons and the Teutons have given the world, at once its best types of physical perfection and its pioneers in the science of medicine

Again, observe that the medicine of each period has been in closest harmony with its intellectual surroundings It has possessed the general qualities of each phase in the evolution of the human mind And itself a creature of human necessity it has in turn created for itself in the public mind an atmosphere luminous in direct proportion to the measure of its own light In an age of barbarism we see medicine as a species of savage sorcery and the popular attitude toward it is one of fear In an age of superstition medicine is the mystery of the alchemist and the popular attitude toward it is that of wonder In an age of ecclesiastic authority medicine becomes oracular and the popular attitude toward it is one of absolute credulty In an age of metaphysics medicine is speculative and the popular attitude toward it is that of dogmatism In an age of experience and superficial observation medicine is empiric and the popular attitude toward it is that which seeks after a sign and demands a specific In an age of science medicine slowly becomes scientific and the popular attitude toward it is that of scepticism of its traditional formulæ and inquiry into the reasons for its faith

Only in the perspective of history can we see these periods outlined sufficiently for the recognition of their essential and separate qualities Since no lines of demarcation lie between them, since insensibly they shade into one another, since the phases of this evolution have not been of coincident development in all communities and through all levels of society, it is not surprising to find the peculiar characteristics of one period invading the next and often exhibiting a remarkable viability It is one of the difficulties with which the philosophy of evolution has to deal, that while the fittest ultimately survives, the unfit makes a desperate struggle for existence Thus we find relics of savagery in the torture of the sick, long outliving the advancement of society into semi-civilization We find the grave cloths of superstition in long-continued use as the swaddling clothes of authoritative medicine We are not so far removed ourselves from the speculative era but that "isms" and "pathies' still persist, and that "systems of human cures or "divine healings still are born and "have their day and cease to be,' proving themselves in their premature decline to be but the "broken lights' of scientific truth We are not yet so far beyond the age of empiricism in medicine, but that we feel the force of the dangerous argument from experience alone and that the multitude of us still prescribe remedies which have a mere reputation of cure which in the vulgar tongue, are good for the ills which ail our patients We are not yet so far advanced into the period of scientific medicine that we trace a cause for every pathologic effect, that we demand to know the physiologic action of every therapeutic agent we employ that we question our daily practice till it gives a satisfactory reason for every custom that we traditionally f[illegible] S[illegible] and so widely distributed has b[illegible] medical profession necessary to meet the growing needs of society that it has sometimes visibly suffered the consequences of its own inertia, rendering it now conservatively slow in response to a moving impulse and again subject to the excesses of its own momental force

Nevertheless, scientific medicine is, I repeat, the still evolving product of an evolutional process which has kept proportional pace with the intellectual development of the race

The evolution of medicine, in common with other subjects of natural development, has not always been a continuous process Occasionally it has suffered a seeming temporary paralysis, and for almost a generation perhaps no important fact of discovery, no new achievement of practice breaks the dead level along which it drags its indifferent way But this apparent arrest of progress proves ultimately to be due merely to some obstacle of error which has barred its upward course, before which it pauses until it gathers sufficient energy to roll the barrier from its path or which now and then, perchance, seems to force it back upon itself and start a retrograde movement which leads about in the end to some broader and better way

And not infrequently does the history of medicine show us that in this, as along other lines of evolutionary force, development has sometimes proceeded by sudden and surprising movements, by the unexpected discovery of some new and widely illuminating truth, by the appearance, as it were, of some massive points of projection in human events or in human life which have given to the few, like Moses, among the mass of men, a glimpse from Pisgah into the land of promise Some of those events and some of those individuals who form these projection-points in the history of the evolution of medicine have only been justly measured or even tardily recognized by the search light of later development Born out of time, they were the abortive products of a false generation in the eyes of their contemporaries, but they were the archetypes of a new era in the judgment of the future Some of them are still unknown, and yet their deeds, which passed unrecognized and are even yet untold, were prophetic of many a modern "new departure" We do not know the names, even, of those obscure professors who conducted a single annual dissection of the human body at Ingolstadt and Heidelberg in the early years of the sixteenth century and who considered it necessary to conduct religious ceremonies after each demonstration before their classes, but it was their spirit which inspired Vesalius, the traveling anatomist of Brussels, and Fallopio of Modena and Eustacchi of Rome whose discoveries have been christened with ' and have immortalized their names

The simple sow-gelder of a German province, who, in 1517, successfully removed the ovaries of his daughter, had little surgical or even veterinary skill to bring to his task, but he deserves recognition, nevertheless, as the nameless author of an operation which has become fashionable, to the weal of many and the woe of some, in these latter days of the nineteenth century

Small honor in his day was accorded to Felix Platter, who, in 1557, insisted upon the psychic treatment instead of the incarceration of the insane, but he it was who led Pinel, in 1801, to remove the fetters from the demented and to teach that mental disease should be looked upon as a brain lesion Prophet he was of a deliverance of the defective classes of society which he anticipated by two centuries and a half of time! Bright projection rising out of the gloom of the professional ignorance of his own times into the clear atmosphere of scientific medicine, his name is deserving of the unconscious worship of the thousands of the hopeless and the helpless who have profited by the evangel he proclaimed!

And among the men whose discoveries have made them famous many there were "of whom the world was not worthy" and who were compelled to wait upon posterity for the recognition they merited As we look back upon their history it seems to us that "there were giants in those days," but they were giants only by comparison with the mass of their fellows among whom they stood They would stand shoulder to shoulder among the scientists of to day They were simply great projection points upon the medical progress of their time, men who laid down the new lines along which progress was made, or from which new departures could come They were not only opportune discoverers, but pioneers, who opened the door to future and sometimes very much postponed research

When Harvey announced the circulation of the blood in 1628, and Malpighi in 1661, discovered the capillary circulation, the facts were viewed as wonder tales by their associates, and not even the discoverers themselves knew what a wonder-world they had opened up to future investigation When Haller, in the eighteenth century, laid down the doctrine of the functional irritability of the nerve-tissues, his colleagues received the new theory with mingled curiosity and suspicion, but they did not know that by virtue of that demonstration, Haller was destined to be called, a century later, 'the Harvey of the nervous mechanism"

When Bichat conducted his brilliant anatomic dissections a hundred years ago, his contemporaries rightly honored him as being the founder of the study of general anatomy, but they did not recognize in him, also, the founder of realism in his profession, they did not see that his scalpel was uncovering facts that were to be used for the overthrow of speculative medicine, they did not read the prophecy of the coming of clinical and laboratory methods in the teaching of the students of to-day in his pregnant words 'Books are merely the memoranda of facts We have living books before us in the living and the dead"

When Jenner discovered the principle of vaccination he was like a miner who has stumbled upon an unexpected gem, whose practical value he puts to a sufficient test, but neither he nor the men who long debated the value of the "find," nor the thousands who have since adopted the practice of vaccination and have minimized the terrors of smallpox thereby, could foresee that his virus might prove, in generations to come, to be the type of many antitoxins, the suggestion of a possibly large field of serotherapy, the forerunner of the gospel of preventive medicine, the faint promise of the proof of the doctrine of immunity from disease

Like all other products of mental evolution medicine has always been responsive to the influence of two forces, the force of attraction from above, incident to the progress of the related sciences, and the force of propulsion from below, incident to the rise of popular intelligence With the beginning of the present century these two forces became active to an extraordinary degree The energy of general scientific development was strongly nascent in the early years of this period It burst finally into a flame which has been burning with increasing and unparalleled brilliancy as the century advanced At the same time were maturing those social and political forces which gave impulse to the magic ideas of Pestalozzi, the father of general education The intelligence which, in earlier ages, had been the heritage of the high-born, began to penetrate downward and leaven the lower strata of society, until it broke forth again, at all levels, in the energy of a popular demand for knowledge The influence of this general rise of intelligence upon the education of the so-called learned professions—learned, hitherto, only by comparision with the masses—who can measure?

These twin forces found the profession of medicine steeped in the atmosphere of speculation and apparently unstirred by the touch of that spirit of practical realism which had its birth in the labors of Bichat But, buried as it was in the schools and systems of speculative thought, it had in it the living germs of scientific development which could not but respond to the quickening influences of the times Not to attempt a general survey of these influences of nineteenth century science, we may just pause to note, by way of illustration, the wide range and varied character of the attractive forces by the aid of which medicine has been lifted to a scientific plane It needs but to mention the labors of Schwann and Lamarck and Schleiden in microscopic botany, of Berthollet and Pasteur in chemistry, of Darwin, Haeckel and Wallace in the philosophy of development, of Faraday, Ohm, Ampère, Seebeck, Edison and Bell in electricity, of Malus in polarization, of Kirchhoff in spectrum analysis, of Fox Talbot and others in photography, of Dutrochet in physiologic chemistry—it needs but to note the names and works of these to see whence sprung the irresistible influences which are helping to make of medicine a science and which have given birth and opportunity to a generation of medical scientists whose names and number and achievements bid fair to rival in brilliancy those of their fathers in general scientific research

With the history of these masters in scientific medicine you will become familiar as you profit by the conquests and discoveries they have made Into this history even of the moderns in medicine it is not a part of my purpose to enter Suffice it that medicine through their labors, is a science It has been difficult for the profession to get away from the speculative tendencies of an earlier day, those hereditary habits still crop out with the persistency of tares among the wheat It has been difficult to outgrow the love for our traditional position of authority in the community, but the day of the oracular in medicine has gone by, the oracle has been found out and it is works, not words, which can win allegiance from the people of to-day It has been difficult to abandon the practice of empiricism, to learn that the argument from experience is a most dangerous one in medicine when all its conclusions rest upon a "variable' quantity in the person of the patient It has been difficult to substitute for these, through the great body of the profession, the exercise of a scientific spirit Even to-day that spirit moves but feebly in the minds of many It has not been easy to learn the unaccustomed lesson of putting "the why" before "the there fore," of distrusting the effect until the cause is clear of doubting "symptoms" and seeking 'signs ' of making conclusion wait upon investigation of applying to the human body the instruments of demonstration, rather than the intuitions of the doctor, of accepting the verdict of the thermometer, the stethoscope, the battery, the microscope, the chemic reagent, the bacteriologic test, aye, even the knife of the autopsy—the testimony in a word, of eye and ear and touch, rather than the feelings of the patient or the supposititious effects of an empiric formula The transition period through which medicine has had to pass has been a slow and tedious phase in its evolution, so large a body, of necessity, moves slowly, but nevertheless it moves No longer the physician is compelled to walk in the half-light of variable experience or in the gloom of metaphysic theories, no longer he treads softly upon the velvet of popular reverence woven out of his fancied possession of occult truths, he stands out in the light of a new day his hypotheses are useful but they must be proven his theories may outrun his practice but they must be supported by facts, he must be able to give to every man the reasons for his faith For the medicine of to day is a science

But, at first, and for a comparatively long period, considering the rapid movement of its later evolution, medicine was, as I have intimated, the science of the masters Indeed, this perhaps is to be accounted for by the very rapidity of its progress Only the master-mind, the mind of exceptional opportunities could keep pace with its league-long steps Slowly the scientific spirit permeated the profession but old and young were compelled, at first, if they received it at all, to receive it at the feet of some medical Gamaliel The masters have slowly multiplied, but, until very recently, facts have been acquired of necessity, at second hand, we have learned the scientific methods of medicine by proxy We of the generation you follow, grew up in a period of pupilage, during which the few were trained in the seats of scientific learning and went out to preach the gospel to the many Students heard with the ear, but did not see with the eye, the structural secrets of the human body if they saw, they did not do the experiments which proved the problems they studied or the operations upon which, in practice, they must soon put untrained hands Their practical work was confined to the use of the scalpel in a single dissection of "an upper' and "a lower," and to the trial of a few chemic reactions in the test-tube for a few short weeks Occasionally they listened to a clinic talk at the bedside of a typical case, or viewed from the distant benches the white aprons of the surgeons and the instruments in the hands of assistants at the operating table or, far less often they gathered, with hungry eyes about the postmortem table in search of a few living facts to be discovered from the dead Some of these imperfect methods, for want of better we still pursue But the age of the masters in medicine, as in other fields is passing by A period of individualism in medicine as in everything else, is upon us There are not fewer intellectual giants than of old, but the medicine of to day demands that all its members shall be of larger mold The many are growing to the stature of the few Science is becoming more available Its instruments are more accessible Its methods are easier of attainment Its results are more easily measured by improved means Its adaptations to daily practice are more numerous and indispensable Personal practical training is more necessary than of old Each must do in the medical science of the future, to a very great degree, what any other has done It is not enough, students in medicine of to-day, that you shall see through others' eyes, you must also see with your own, it is not enough that demonstrations shall be made and tests done for you, you must do them for yourselves, it is not enough that shall know the names of drugs, you must be able to recognize them, you must not only learn their action, but you should *see* it, you must not only be able to tell the constituents of the body fluids and tissues, but you must be able to analyze them, you must not only learn by ear the structural peculiarities of the tissues, you must be able to differentiate lung and liver and nerve tissue, under the microscope, you must not only be able to count a pulse, you must be able to study its qualities, you must not only know the meaning of heart sounds, you must be able to discover them and read them aright, you must not only be able to take temperature, but you must understand its production, its regulation and its means of loss you must not only understand the principles of dietetics and food-preparation, you should be able to put them into personal practice, you must not only learn the principles of obstetrics, but you must practice them individually under the guidance of your teachers you must not only witness operations, you must *do* them on the patient or on the cadaver, you must not not only know the peculiarities of pathologic products, you must be able to make their differential diagnosis under the glass you must not only know the names of disease germs, you must be able to recognize their forms, you must see them not only in the persons of their victims, you must rear them in the culture-tube, you must not only master the details of physical diagnosis, you must be able to apply them to disease at the bedside or in the clinic The opportunity to accomplish these things is enlarging with every passing year It is the heritage which the masters of the past have bequeathed to the students of the present

Ladies and Gentlemen I have heard these things called the adornments of medical teaching A student informed me but a few days ago that her preceptor had advised her that these accessories were "nice but not necessary" They *are* embellishments, it is true, of the medical practice of fifteen or twenty years ago, but they constitute the warp and woof of the scientific medicine of to day For the attainment of this ideal education, it is necessary for the teacher to come as closely as possible into contact with the individual student The didactic instruction of large classes is a means of time saving, but for recitations and reviews, for laboratory exercises, for demonstrations, for purposes of bedside and clinic diagnosis, for obstetric attendance, for the witness or the performance of operations, in short, for all forms of practical work, these classes should be divided into small sections Upon the adoption of such a recitation system and upon the initiation of such section work in several *clinic* branches this college is to be congratulated Its fuller extension to the entire laboratory and clinic system and even to the surgical operating room is to be desired It is possible for a class of ten or fifteen students to witness an operation with profit, but the hours spent by large crowds of students in a surgical amphitheater are largely wasted and could be spent by the majority of students more profitably over a text-book descriptive of the operation they are seeking to witness A multiplication of laboratory assistants and clinic instructors is involved in this plea for a more elaborate system of sectional work, it means a larger equipment and a larger expenditure of material, but its adoption is in the path of progress in our professional schools As a step in the same satisfactory direction we welcome the partial abandonment of the final examination system and the substitution for it of oral recitations throughout the term and at the close of the college year

In a word, medical education is to be conducted, so far as possible, in the individual rather than in the mass It is to be less didactic and more practical It is to be less in the lecture room and more in the laboratory, in the hospital, in the dispensary and in the clinic Leaders in medical science, teachers in medical thought there must always be, but each man and woman who essays to study medicine must be a master of his or her profession A new relationship exists between the leader and his followers, between the teacher and the taught, a relationship of companionship History is repeating itself in a return to the more conversational methods of the Socratic system The spirit of mastery which put into the mouth of the teacher that voice of dogmatic authority which became the old prophets of tradition, "Thus said the Lord," is passing away and in its place we hear the voice of more philosophic, more reasonable invitation "Come now and let us reason together" To such a companionship of science, to such an intimate association of research, to such a leadership upon the part of the teacher and to such a following upon the part of the pupil, to the immediate possession of a place, at the very outset of your college career, in the profession of scientific medicine, on behalf of my colleagues, I welcome you Personally, I do not care to what school of medicine you belong You may attach yourselves to any or to all schools you will be safe, and your future patients will be safe, under any banner, if only you are scientists in medicine If you are not, it matters nothing to what school you claim allegiance, you will be an eventual failure If you have come here prepared to work with us and for us, as well as for yourselves, determined to make yourselves, not merely practitioners of medicine but medical scientists, I extend to you, in the name of this University, the right hand of scientific fellowship If one of you has come here to purchase a diploma and to gain it by the shortest and easiest route to its attainment, I want to bid you, in the name of medical science, to find a less exacting and more lucrative calling or, if you must seek it upon this commercial basis, to go where diplomas are for sale

But, believing as I do, in the sincerity with which you seek admission to this honorable and scientific profession, let me ask you to begin your career with a clear recognition, not only of the demands which it will put upon you at the end of your college course, but also of the demands which it puts upon you, as men and women, as physicians in the making, now If you are to be a medical scientist you must be equipped to become one If you are to be a master among men you must have a due preparation for the mastery of your science A pyramid can not be reared upon the dimensions of its apex A new education in medicine is before you A new standard of requirements measures you If you are to survive in the fierce struggle which awaits the competitors of to-day in this calling of ours, you must be fit to survive. If you are not, that struggle will surely crowd the unfit eventually to the wall. The success of our sowing will depend upon the quality of the soil you offer to the seed. The character of the harvest you yield, will reflect upon the prior preparation of the brain soil you bring to the seeder. You will join with me, I know, in congratulating this college and the university to which it belongs, that it has already planned to safeguard, still further than it now does, these portals to the profession by demanding of its matriculants a higher measure of preliminary culture than they have been required to possess in the past. The higher evolution of the science of medicine must depend upon the quality of the men and women who gather in its institutions of learning and graduate from their halls. The medical science of the future will be the product of the labors of the profession, not merely among its masters, but in its mass.

ORIGINAL ARTICLES

REPORT OF ONE HUNDRED CASES OF EXTRACTION OF HARD CATARACT

Read in the Section on Ophthalmology at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta, Ga., May 5-8, 1896.

BY LYMAN WARE, M.D.

CHICAGO, ILL.

It is not unusual for a surgeon, whether East or West, at home or abroad, to consider his special method of extraction of cataract superior to that of any other. Certainly, when one's cases are somewhat limited, it is infinitely better to become perfectly familiar with a special method and adhere to it as closely as possible, and whenever changes are made in order to accomplish some definite object, they should be gradual. The operation to be chosen should be the simplest and easiest of execution.

The loss of an eye means much to a patient, whether he be rich or poor. Relatively speaking, it is as unfortunate for an oculist to lose an eye as for a surgeon to lose a life. From Daniel's time to the present it has ever been sought to simplify the operation. I may be considered too conservative, but the results I have obtained will, I am sure, compare favorably with those of any other method, and I think that in the future they will be better than in the past for the simple reason that "practice and care make perfect."

When there is no complication, that is, no disease of the eye aside from the cataract, and when the patient is reasonably tractable every operation ought to be a success. A number of years ago I reported (in the *Chicago Medical Ex.*) Von Jager's method of operating, which impressed me most favorably. Many of you can recall the grace and ease with which he operated, seated, after the manner of Daniel, on a stool directly in front of, and somewhat higher than the patient, who faced a large window, he considered it play to remove cataracts. His methods seemed to me ideal. The first twenty-five cases operated upon, I attempted to follow them in most respects. I used his concavo convex knives, and cystitome, but instead of facing, I found it easier to stand behind the patient who either lay upon a table near or sat in a chair facing a window. A single and simple obstacle caused me to substitute Von Graefe's for Von Jager's knives. However simple it may seem, it was almost impossible to get Jager's knives sharpened in this country. After trying a number of instrument makers in Chicago and New York, I finally became discouraged and wholly discontinued their use. No knife, in my experience, makes so clean and even an incision as Von Jager's when in perfect condition, and no wound heals so quickly.

The cases here reported were charity patients. Preliminary iridectomy was done in most of the cases in those where the cataract was fully ripe and the patients came from a distance, the extraction was done within a week or ten days after the preliminary operation. When the cataract was *not* fully ripe, or the patient lived near, a longer interval was allowed between the two operations. Usually only a small portion of the iris was excised, and as it was always under the upper lid, there was no deformity nor was there, after the lapse of a few weeks, any complaint of dazzling or glaring light. The subsequent appearance of the eye was that of a very moderate coloboma. But should some deformity exist, what is that compared to useful vision? Truly, more time is required of both operator and patient, but what is time to the doctor when an eye is at stake, or to the patient who may have groped in darkness for years? Then, too by a preliminary iridectomy at least two important questions may be solved—how the patient, and how the eye is going to behave. One is warranted in stating that the first operation will be the more severe and consequently if the patient is tractable and quiet during the first, there is little doubt that he will be equally so during the second. If there is any predisposition to conjunctivitis or inflammation of any form, the preliminary iridectomy and subsequent treatment will most probably develop it, in which case the extraction would be deferred until the disease was completely cured. Patients were not operated upon until they became somewhat familiar with the surroundings, that is, one or two days after their admission. The preparatory treatment consisted in giving a slight mercurial laxative and bath the day before the operation, and thoroughly washing the head. The immediate treatment consisted in irrigating the cul-de sac with a solution of mercury bichlorid, 1 to 5,000, and then with a saturated solution of boric acid, followed by the instillation of a few drops of a 4 per cent solution of cocain every three or four minutes until the anesthesia of the cornea was complete. As a rule, but three instruments were used—fixation forceps, knife and cystitome. An assistant lightly raised the upper lid while the corneal section was being made which usually included the upper two-fifths, and was made in the cornea at the sclero corneal junction. In cases where the lens was very large and hard the section was made even larger including nearly one-half of the cornea, as was originally advised. I am sure that a small section is a most serious mistake and probably causes more complications and the loss of more eyes than all others combined. The capsule was uniformly opened in the periphery after Knapp's method, except in those cases of hypermature cataract, and where the capsule appeared tough or showed calcareous deposits when the lens was removed with the capsule by means of Föster's capsule forceps. It is to be regretted that it is not always possible to determine in advance when a lens can be removed in its capsule as the result is so much better than when the capsule is incised and

the lens only extracted After the completion of the corneal incision, the fixation forceps are removed and the further aid of an assistant is hardly necessary Slight pressure is made upon the peripheral lips of the wound, then, in many cases, the natural contraction of the lower lid will expel the lens, but should it not, gentle counter-pressure by means of the thumb applied upon the lid will be amply sufficient The eye is then thoroughly washed with a warm saturated solution of boric acid, and should there be any lens matter remaining it is generally coaxed out in the same manner A small pledget of lint or cotton is saturated with the boric solution and laid upon the eye, over which absorbent cotton is placed, just sufficient to keep the lids well closed, and feel comfortable to the patient After the gauze or woolen bandage is applied the patient is allowed to walk to his room, and is put immediately to bed, where under ordinary circumstances he remains for twenty-four, or preferably forty-eight hours The room is not darkened, but bright or glaring light excluded Should the dressing of the eye be uncomfortable, it is changed and applied more lightly Eighteen or twenty hours after the operation the bandage is removed, the dressing carefully inspected, and should there be no unfavorable indications the eye, unopened, is well bathed with the saturated boric or bichlorid solution, and a few drops of a 1 per cent solution of atropia is dropped into the inner canthus of the eye Should there be no complications the eye is similarly dressed every twenty-four hours until the third or fourth day, when the bandage is removed and a single muslin strip tied over the eye for a day or two, when a shade is substituted and worn as long as the light is unpleasant The average length of time in the hospital was one month, which may seem rather long, but as many lived at a distance, it was deemed expedient to keep them as long as possible in order to perform discission should it be necessary, this was done in about 25 per cent of the cases Patients were not confined to bed longer than twenty-four hours if they wished to sit up, nor to their rooms more than three or four days It was, however, generally found that patients recovered more rapidly if kept reasonably quiet the first few days or week Patients living in the city were frequently discharged ten days or two weeks after the operation

Discission, which was usually done with Knapp s needle knife, was performed usually from three to six weeks after the extraction, and uniformly improved vision

I would especially desire to call attention to the unfavorable cases, as the consideration of such is sometimes more profitable than that of the successful ones

Case 15 —Mrs C Peterson, age 65, senile cataract, blind ten years, chronic conjunctivitis of both eyes for several years and dacryocystitis of the left for three or four years general condition feeble She was placed at once upon tonics and a generous diet The conjunctivitis was treated with astringents - mild sulphates and weak solution of nitrate of silver—the dacryocystitis by Bowman s method and injections of solution of bichlorid of mercury, 1 to 4 000 and bougies of iodoform and zinc. After a month of such treatment the general and local conditions fully warranted the cataract operation, which was performed on each eye, one week intervening between the operations She made a good recovery without an untoward symptom—V =20 100 in left, right in which there were corneal opacities and calcareous lens, no improvement Two weeks after the last extraction she was allowed to go to her home, with the understanding that she would return in a month or six weeks On her return there was a slight discharge as a result of the chronic dacryocystitis, but so slight I did not think it possible, after a thorough irrigation of the sac and duct with the bichlorid solution, to cause any trouble, consequently I did the operation of discission on left eye, hoping to improve her vision The operation was performed in the usual manner and gave every promise of success, yet within twenty four hours distinct symptoms of panophthalmitis appeared, and the patient lost her eye and almost her life Subsequently the operator was confronted with a suit for damages Previously I had considered the operation of discission so simple and free from accidents as hardly to give it a thought

Case 29 —Mrs M Johnson, age 64, senile cataract both eyes, left fully, right partially mature After preliminary iridectomy of the left, the lens was easily extracted without any complication, and until the fifth day there was not an unfavorable indication On that day she complained of considerable pain in the eye and temple On examination the eye was found to be much injected, the anterior chamber very shallow and the wound reopened In explanation of the greatly changed condition she stated that the resident physician, in changing the dressing the evening before, had in some manner hit the eye, which had immediately caused excruciating pain Chronic irido cyclitis developed, and as the opposite eye was endangered by sympathetic inflammation, the diseased eye was advised removed

Case 23 —Shodd C , aged 47, extracted left eye three weeks after iridectomy Operation normal except incision somewhat small for the hard, unyielding lens, requiring more than the usual pressure to force it out Five days after the operation the patient struck her own eye Irido cyclitis followed and the eye was enucleated one month later Although the patient distinctly stated that she hit her eye, it is possible that the pressure and consequent injury to the iris at the time of the operation may have been the principal or sole cause or the trouble

Case 30 —Tindall M , aged 62, senile right eye, motion, perception and projection fair Extracted two weeks after iridectomy Lens adherent, removed with hook, some vitreous was lost Plastic iritis and occlusion of the pupil followed

Case 60 —M , aged 58 Senile bilateral R M One week after operation dressings were removed by patient during the night The wound reopened and caused some prolapsus, which was excised Good recovery resulted with fair vision

I much regret that in my notes of cases more details are not given When I began to operate I was guided and much influenced by V Arlt's teaching, that vision was the *one* object, and he said (Knapp's Archives, Vol x), "Were I to be operated on for cataract I would rely on that method which, on the whole, assures the greatest chances for recovering vision—more or less good vision, and all that sort of thing, is secondary so far as concerns the choice of method' Certainly with the majority of those operated upon and here reported, vision of any kind was the great object Yet I am confident, if care and time be taken to avoid complications, and the patient is kept under observation for a few weeks to determine whether discission may be necessary or not, good vision can be secured just as easily as moderate In reviewing the cases, two weeks was the average time intervening between the preliminary iridectomy and the extraction I have omitted in this calculation those cases where iridectomy was done to hasten the ripening of the cataract The average time of each patient in hospital was about one month Many were kept longer than absolutely necessary, as they came from a distance and it was considered best to keep them long enough to fit them with glasses and also to perform discission should it be advisable A few living in the city were discharged from the hospital from two to three weeks after the extraction The average age was 60, varying from 14, pyramidal cataract, to 85, of which latter there were several The cases 14, 23, 29 and 30, four in all, were failures, and failures much to be regretted as they were all preventable Cases 9, 15, 16, 17, 22, 24, 40 39, 41, 42, 52 and 53, total 12, were complicated with choroidal trouble or corneal opacities, and little hope was given that vision would be improved, so that in estimating the number of those who were benefited by operation, these should be excluded In brief, we have in the hundred cases four complete failures One only counts fingers at five feet, partial failure, which would be five failures, 5 per cent Twelve complicated cases, abnormal condition, 12 per cent Twelve cases in which there was no record as to vision, but noted that they made a good recovery, which would mean 20-200 or better, so that we have

12 cases,	1 10 *or better*	13 per cent
4 "	1 10	4 " "
9 "	1 5	11 " '
16 "	1 4 or better	19 " "
12 "	1 3 or better	14 " "
21 "	1 2	24 " "
7 "	2 3	8 " "
2 "	1 1	2 " "

I desire to express thanks to Dr L Weber, resident physician, who kindly aided me in arranging the above cases

DISCUSSION

Dr W T **Montgomery**, Chicago —It is only in very exceptional cases that I make a preliminary iridectomy I do not perform extraction under two weeks from the time of the first operation If the conjunctiva is healthy I do not use the bi chlorid solution, 1 5000, because it so frequently produces decided irritation Instead I irrigate freely with boric acid solution before and after operation I prefer the speculum to any assistant to keep the lids separated during an operation I do not make the corneal section so large as recommended by Dr Ware, but it is better to make it too large than too small If the patient has useful vision in one eye I only bandage the eye operated upon and allow the patient to sit or recline in a darkened room If the eye is comfortable the first dressing is not disturbed until the second or third day and as a rule I substitute a shade for the bandage on the sixth day

Dr A C **Corr**, Carlinville, Ill —I am of opinion that in all operations in which an iridectomy is to be made that it should be preliminary from the fact that it is not complicated with the dangers of the manipulation of the extraction, and on the other hand when the extraction is made it is not complicated with the dangers of an iridectomy I regard the preliminary iridectomy as very important and necessary to an ideal operation The teachings by professors and the books is almost all against the preliminary iridectomy, and it should not be so

Dr J A **White**, Richmond—If you are working only to secure to the patient every possible chance of vision, it is advisable to do a preliminary iridectomy in every case It is not always practicable for the reason that the longer you extend the time of treatment the more trouble you will have from the patient who wants to get through the case as soon as possible You should have as large a section as possible so as to have an easy extraction of the lens It should be as large as can be, even to the extent of one half of the cornea I always make mine two fifths of the cornea, keeping entirely within the corneal tissues As to antiseptics, my method is to prepare the patient the day before I intend to operate I first have the face thoroughly washed with soap and water, then sterilize the skin about the eye with solution of bichlorid 1 2000 It is impossible to thoroughly sterilize the conjunctiva, but we are not afraid of producing irritation with bichlorid After the washing we introduce into the conjunctival sac a 1 3000 salve of bichlorid, and then sealing up the eye leave it until the next day If there is any secretion present when the eye is opened we do not operate During the operation we use the instru ments sterilized with bi chlorid It has been my experience occasionally to remove the whole lens with the forceps on catching the capsule If I find any difficulty in delivering the lens I give the patient the benefit of an iridectomy so as to make the delivery free and easy I have found the cortex remaining was not so dangerous as supposed It is nearly always absorbed and I would rather take the chances of a secondary operation than to prolong the time and subject the patient to extra danger Since using the forceps I have had better results and have done fewer secondary operations I do not approve of permitting the patient to walk about

Dr H B Young, Burlington, Iowa—As a result of iridectomy, either preliminary or at the extraction, is it not possible that the stump of the iris is more often incarcerated in the wound than we commonly suppose? As one of the complications of cataract extraction I would ask for information as to the occurrence of acute glaucoma In one of my cases where atropia was used as suggested by Noyes, acute pain appeared twelve hours later with the usual symptoms of acute glaucoma Instillations of eserin were used and a good recovery made

Dr A W Sterling, Atlanta—I have had under my care one case of glaucoma secondary to cataract extraction One dozen or more of these cases recorded have been investigated by Nordenson, and he found the causes to be chiefly prolapse of the capsule or the vitreous When they appear suddenly they are usually due to the healing in the wound of a bit of capsule which blocks the flow of the fluid The case I had was due to secondary needling after extraction When the needles are pulled out too rapidly a little vitreous may escape with the fluid and, becoming fixed, pulls forward the contents of the eye and blocks the angle

Dr G C Savage—The ideal operation has not yet been perfected, that is, the extraction of the lens in its capsule without iridectomy If some man will devise means of separating the lens in its capsule from the suspensory ligament, the operation will be complete I always commence with the intention of doing a simple extraction, and regret to have to perform the combined operation I have the things ready, and often have to do the combined operation I want a large incision to include as much as one half of the circumference

Dr A W Calhoun, Atlanta—I do not know that we have cataract in this country more than in other portions of the world, but we certainly operate more I have operated upon 1,300 cases within the last twenty years I formerly commenced with the intention of doing a simple extraction, but I now prefer an iridectomy I very rarely have occasion to do a secondary operation I take a great deal of trouble to get out all the cortical substance and usually have a very clear pupil Previous to the use of bichlorid I thought I was doing very well if I had 95 per cent of successes, but with its use I rarely have any trouble whatever I use it in the strength of 1 to 10,000, washing out the sac before, during and after the operation, in fact, keeping the field perfectly flooded with the solution I see my patients twice a day for the first week I keep them in their rooms longer than is the custom I have lost probably not more than one case in the last two or three hundred I do not always get 20 20 vision, but 20 200 is very good vision and enables the individual to do ordinary work I used to think that a little loss of vitreous was a serious thing, but I have found that a slight loss amounts to nothing The only danger is that when once started, you can not predict where it will end In some cases I have imagined that it proved of service, for it broke up the posterior capsule and left a window there I always endeavor to avoid such a thing I use a very weak solution of cocain, ½ per cent, and it is just as satisfactory as the 4 per cent solution

Dr R L Randolph, Baltimore—It has been shown that the weak solutions of bichlorid have no effect upon the organisms The action of these solutions is not killing but getting rid of them mechanically, and we will have just as good results, if we boil the solution, whether it is bichlorid, salt solution or plain water I boil my instruments, except the knife, which is kept in absolute alcohol until ready for use, then washed in boiling water A solution strong enough to kill germs will produce irritation I have operated on 160 or more cases, and my best results as regards vision have been those in which preliminary iridectomy was performed

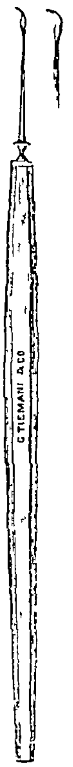
A NEW KNIFE FOR SECONDARY CATARACT

Read in the Section on Ophthalmology, at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5 8 1896

BY A J ERWIN, M D
MANSFIELD, OHIO



In presenting a new instrument to the American Medical Association it becomes necessary to show that such an invention is needed to fill a want It seems to me that heretofore we have not had an implement for the convenient removal of the opaque capsule, or so-called secondary cataract Often, on account of its flaccidity or toughness, the ordinary needling of the capsule will not clear the pupil We are frequently obliged to open the eye and remove the capsule with the forceps The knife that I herewith present is about the size of the smallest discission needle It is curved about 50 degrees on both the edge and the flat, with both edges and point sharp Its action is somewhat corkscrew-like By a rotary motion of this knife one can tear the capsule into fragments if necessary, or draw it to the corneal margin and extract it I have found it a very useful instrument It was made for me by George Tiemann & Co, New York

ACUTE NON-SYPHILITIC CHOROIDITIS IN YOUNG ADULTS

Read in the Section on Ophthalmology at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5-8 1896

BY HIRAM WOODS, Jr, M D
ASSOCIATE PROFESSOR OF EYE AND EAR DISEASES, UNIVERSITY OF MARYLAND BALTIMORE MD

It has frequently been noted that of all eye structures the uvea is most apt to show systematic disease The iritis, cyclitis and choroiditis of syphilis and rheumatism are matters of daily observation The liability of the iris to become inflamed, in gouty subjects, after such slight trauma as simple cataract extraction, makes one chary in pressing operation upon such persons The choroid is the favorite place for ocular tuberculosis Metastatic infection from sepsis, typhus, typhoid and, more rarely, remittent fevers, from cerebro spinal meningitis, most commonly appear in the choroid Now and then one reads of functional disturbances in the iris or ciliary structures, attributed to digestive or sexual disorders Again, *it is from primary choroidal growths that* metastasis is most apt to result When one examines treatises upon diseases of the eye for the etiology of choroiditis, he finds comparatively little As a rule, after a more or less thorough description of the appearance of the exudate, clouding of the vitreous, floating opacities absorption of infl [illegible] aterial with restoration of function, or [illegible] lopment of atrophic areas with heaped-up pigment, producing scotomata, one reads "The most common cause is syphilis, inherited or acquired Sometimes *no definite cause can be assigned Exceptionally*, choroiditis is associated with malnutrition, scrofula, chlorosis and anemia" This is copied from the recent edition of Juler's book and is a fair index of others That routine office examinations reveal old choroiditis not due, so far as can be discovered, to any of the commonly accepted causes, can not, I think, be denied Exclusion of syphilis, inherited or acquired, is not always easy Lesions, characteristic of the disease, excite doubt concerning the history rather than stimulate search for less common or doubtful causes All of the cases narrated below are open to this objection Careful inquiry was made, and the presence of an eye disease, thought to be usually due to syphilis, but not essentially characteristic of it, was the *only reason for suspecting its presence*

During the past eighteen months I have seen in private practice five cases in the acute stage of the first attack, and two undergoing relapses of old choroiditis Five were in females, two in males Their clinical history is appended

RELAPSING CASES

Case 1 —Miss D , 27 years of age, seamstress, was referred to me in February, 1896 For six weeks the right eye had been defective with constant floating clouds Vision was 10-200 Ophthalmoscopic examination revealed muddy vitreous with floating specks, an area of choroido retinal exudate, to the temporal side of the fovea, while more externally was a mass of pigment suggestive of a former attack She had fair health save in one respect, menstruation Since its commencement at the age of 15, this function had been irregular Sometimes six or eight weeks would elapse between periods About Christmas *after several days hard work and on the third* or fourth of menstruation, she noted the eye symptoms Improvement has been steady and distant vision on April 24 was 20-40 There is still some vitreous clouding

Case 2 —Miss E D , 21 In 1888, when this young lady was in her 13th year, I attended her for left purulent ophthalmia How the child contracted this disease was difficult to explain, though later her family physician attributed it to infection from a servant, who, he had reason to believe, had gonorrhea at the time The eye recovered with a small peripheral corneal scar If there was any choroidal disease, acute or chronic, my ophthalmoscopic examination did not reveal it In 1892 she consulted me again for asthenopia Correcting H As she obtained 20-15 vision in each eye At this time when she was 16 years old, I found in the upper and inner quadrant of the left eye a patch of choroidal atrophy The family history was good, the girl's health perfect, and had been since 1888 Menstruation had, in the meantime, been established Later, in 1892, Miss D consulted me for "floating specks" and dim vision in the left eye The vitreous was found slightly cloudy and vision 20-40 This attack had come on suddenly during a menstrual period She soon recovered This past winter she has had a similar experience At neither time was there a fresh exudate but vitreous clouding and floating opacities were unmistakable

PRIMARY CASES

Case 3 —Miss G , 21 years old, a robust, athletic young lady, called April 14 On March 14, she suddenly lost the sight of the left eye Vision was 20-200 on April 14 The vitreous was cloudy, and examination difficult I was able, however, to see the retinal vessels, hidden in part of their course, with a grayish yellow choroido retinal exudate at the temporal side of the fovea There was no hemorrhage I learned that on the morning of March 14 menstruation had appeared Miss G had never remained indoors at such times and took an unusual amount of exercise that day During that evening she had a severe headache, and found that her sickness had ceased Shortly afterward the dimness of vision was noticed Menstruation reappeared the following day, and she had expected the eye would soon get better To day (April 29) vision is 20-100

Case 4 —I am somewhat doubtful about the diagnosis of this case, but its history, and the ophthalmoscopic picture justify its narration

A lady, 22 years of age, apparently in perfect health, was brought to me in March, for an explanation of blurred vision in the right eye Visual acuity was 20-50 right, 20-15 left, the former unimproved by glasses A week previous, toward the *close of menstruation, this had been noticed Slight* haziness of the vitreous with a blurred appearance of the fovea a small deep red, sub retinal spot, apparently a hemorrhage It slowly disappeared, and in three weeks vision was 20-20

Case 5 —Mr E , 25 years of age, lost sight in right eye suddenly in September, 1894 Vision was barely perception of the moving hand Densely clouded vitreous, blurred retinal vessels and an area of foveal choroido retinal exudation were easily seen The case has resulted in a central atrophy with scotoma Eccentric vision now is 20-70 Mr E is an active man He is entirely free from any of the recognized causes of choroiditis The only associated condition I could discover was a tapeworm He said that several ineffectual attempts had been made to dislodge this tenant Except at these repeated therapeutic onslaughts, his intestinal possession had not worried him He has, I believe, recently gotten rid of it

Case 6 —Mr R , 33 years of age, was sent me February, 1896 For two weeks right vision was blurred It was 20-50 A choroido retinal exudate in the upper and inner quadrant with *hazy vitreous explain his symptoms This is slowly under* going absorption On April 30, distant vision was 20-30 Mr R is in active business involving large responsibilities He enjoys good health, but has recently suffered from what he terms "nervous dyspepsia," occasionally washing out the stomach. I could find no other disturbance Tuberculosis and syphilis seemed positively excluded

Case 7 —J J , 27 years of age, was sent to me in September, 1895 Vision in the right eye had become suddenly blurred ten days previously Mr J was an engraver by profession and in robust health In the lower nasal quadrant there was a yellowish white exudate, associated with muddy vitreous and floating opacities Vision was 20-60 A scotoma was easily located in upper temporal field This has remained, corresponding with the atrophy in lower nasal fundus Central vision now is 20-20

Treatment in all of these cases followed the usual lines Purgation and diaphoresis in the early stage, with leeches in one Case 5 Later tonic, alterative remedies were administered, as iron, corrosive chlorid

There is a more or less general recognition of functional relation between the eye and the female pelvic organs That affections of one can influence the functions of the other is seen in the eye symptoms, sometimes occurring at the menopause, and less frequently at menstruation Some gynecologists recognize the need of correcting "eyestrain" when refraction error exists, if certain forms of uterine disease are to be cured Dr Moseley has recently called my attention to a paper by Dr Matthew D Mann of Buffalo, read at the Baltimore meeting of the American Gynecological Society in 1895, setting forth this necessity These reflex disturbances, interesting as *they are, do not, however, belong to my subject*

Less generally an inflammatory condition of the eye caused by pelvic disease is recognized The following from Soelberg Wells (p 329), presents it better than I have found elsewhere

"An important exciting cause of idiopathic cyclitis, especially of the serous form, is found in disease of the uterus accompanied by disturbance of the menstrual function DeWecker thinks this is the reason why spontaneous irido-cyclitis occurs with so much greater frequency among women than men The restoration of the menstrual flow in these cases exerts a beneficial influence upon the ciliary inflammation Pregnancy often causes relapses in cases of old chronic cyclitis In girls from 16 to 20 years of age a mixed form of serous and plastic irido-cyclitis or choroiditis is frequently encountered, almost constantly associated with either amenorrhea or irregular menstruation and chlorosis This form of inflammation is also not an uncommon complication of the menopause, especially in those women in whom the climacteric period comes on unusually early"

Trophic changes through reflex nerve influence, metastasis, or a third trouble acting as common cause suggest themselves as possible explanations Dr Mann (loc cit) speaks of insufficient urinary secretion and lithemia as possible causes of pelvic disease He traces this not infrequently to intestinal troubles In all of my cases urinary examination was negative, but considering the liability of the uveal tract to inflammation in gouty or rheumatic subjects, one thinks of the possibility of the same cause producing both eye and pelvic disorder The frequency with which we find evidences of old choroidal inflammation, of which the patient can often recall nothing, and the identity of the ophthalmoscopic picture resulting in cases we treat, with that found in untreated cases suggests the question of the value of therapeusis Vitreous clouding causes visual defect When this clears, the patient has recovered or been cured just in proportion to the absorption of the exudate, or the distance of the resulting atrophy from the fovea Syphilitic cases, it is recognized, promise best from a therapeutic standpoint, but even here it is from relapses that we aim to save our patient, rather than from the natural result of the lesion present In so-called idiopathic cases, if associated troubles of any kind can be found in a considerable number, etiologic relation is suggested To find and remove this factor, if possible, should be the aim of treatment

IDIOPATHIC CHOROIDITIS

Read in the Section on Ophthalmology at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga , May 5-8 1896

BY ADELINE E PORTMAN, M D

Physician of Eye and Ear in Woman's Clinic Assistant in Eye and Ear Department of Central Dispensary and Emergency Hospital

WASHINGTON D C

Idiopathic choroiditis is a subject on which we find, in text-books, almost nothing to aid in diagnosis of the disease which has had so little investigation by the busy oculists of the present time

As you know, the choroid consists of the vascular parenchyma, an exterior coat of endothelium upon its scleral surface, and the *lamina vitrea* Upon the latter lies the pigmented epithelium which is assigned to the retina, though it always suffers when the choroid is affected The blood supply of the choroid is from two groups The capillary vessels, which lie nearer the inner surface, and the venous to the outer The chief blood supply is from the short, posterior ciliary arteries After entering near the optic nerve and piercing the sclerotic they pass into the choroid, then branch, forming the capillary network of the choroid, ending in the indented margin of the *ora serrata* Long posterior and anterior ciliary arteries send small branches to meet these vessels The venous blood, collected from the capillaries into the *venæ vorticosæ*, leaves the eye through the sclerotic The parenchyma has an abundant nerve supply from the long and short ciliary nerves and a network of pale nerve fibers in the choroid which accompany the blood vessels and have many ganglionic cells They end in the capillary layer From the abundant nerve and blood supply we understand how rapidly an inflammation can extend, and why it must always be considered a grave condition

It is doubtful if hyperemia of the choroid can be demonstrated or diagnosed by the ophthalmoscope, for in long neglected ametropia uncorrected, and in prolonged eye strain we observe a flannel-red appearance Idiopathic choroiditis has no subjective symptoms, there being pain only in the purulent forms, or where there is iritic complications The disturbance of vision is in direct relation to the situation of the lesion and amount of atrophy In the period of progression all stages, from the first yellowish spot of exudation to complete atrophy, may be seen

The ophthalmoscopic signs which distinguish choroidal opacities from those of the retina, are that the retinal exudation spots have a more brilliant color, their opacity denser and their contour is defined by very fine radiating striæ, which correspond with the direction of the nerve fibers, the vessels are tortuous and partially disappear under the opacities The vessels pass freely above choroidal opacities, without change of appearance, the exudations show a dull yellowish reflection, the atrophic spots are brilliant, marbled, bluish, due to the denuded sclerotic Instead of a dull red ground, large vessels may be manifest as reddish and yellowish-red stripes, forming a lace work, between which are dark, intervascular spaces lozenge-shaped, caused by absorption of the pigment and capillary layers In certain instances this condition is physiologic and is commonly seen in the space downward and inward from the disk The large vessels of the choroid stroma pass in a sinuous manner across the eye ground, bringing into distinct relief the pigment connective tissue cells of the choroid proper, which lies beneath them We also find this condition in myopia and in the so called stretching eye, where hyperopia is becoming myopia in glaucoma, and is at times associated with pigmentary degeneration in retinal diseases This atrophy of idiopathic choroiditis does not disturb the vision necessarily, at first, to any appreciable extent, though complete loss of visual acuteness is the ultimate result Usually the gradual diminution of visual power creeps on so insiduously, that the patient only becomes aware of it after it begins to interfere with their usual vocation, and by an attempt to have glasses fitted to improve failing vision Nettleship gives accounts of what he calls "generalized choroidal disease," in persons who have not had or inherited syphilis, but believes it due to scattered hemorrhages into the choroid, occurring repeatedly at different dates, leading to patches of atrophy with pigmentation, which he has found mostly in young males Hutchinson claims that a disseminated choroiditis affecting both eyes is found occasionally, as a family disease, independent of syphilis, and connected with diseases of the nervous system To this class of cases, of nervous origin perhaps, belong the cases found among the overworked the physically enervated man, the slaves of the everlasting day-book and ledger in large business houses, where long years of close, hard application added to the ever growing demands of a family that brings an ever increasing worry, where little exercise and less fresh air combine to sap the failing strength and low vitality, also that class of overburdened women who have spent their lives in the hardest work, the mothers of large families, who from rapidly repeated pregnancies and overstrained system, in vainly trying to bear the endless burdens their lives impose, have exhausted all [illegible]erve of [illegible]hysical and nervous force they may [illegible]hemselves at the menopause with [illegible] nd a mental balance trembling on the verge of insanity

Again, among the old, who have been exceptionally healthy and strong during a long life, find the vision growing strangely dim, in whom there is no cataract, who go from one oculist to another in a vain attempt to get glasses to improve their sight, we find the large patch of choroidal atrophy, usually near or partially including the disk, a condition of old age apparently But not only in the old and middle-aged do we find this sad enemy, for Magnus in 1886 made a report giving the results of his investigation of sixty-four institutions for total blindness The number of those affected with idiopathic choroidal disease under 20 years of age in the 1,060 examined was 75, while in the 551 cases of congenital amaurosis were 48 due to the same cause It also appears frequently in the 2,528 cases reported by Schmidt-Rimpler, Hirshberg, Magnus, Landesberg, Seidelman and Katz, 276 were of idiopathic choroidal disease, showing it to be an enemy of all ages May it not be possible by a careful investigation into the cases that are met with before much destruction has taken place, to arrest its progress and thus save the few who can be benefited? Let us remember that all choroidal diseases are not specific and should not be treated as such May not continued attention and watchfulness save the most valuable faculty we have, to some few at least? And though this form of choroiditis may be the result of a dyscrasia, so is trachoma, but that does not make trachoma any less a disease

DISCUSSION

Dr **Herbert Harlan**, Baltimore—I have seen quite a number of cases, and have now one under treatment in a very healthy young woman, who, while there is no suspicion of syphilis, has taken one sixth of a grain of bichlorid of mercury hree times a day for several months, and her vision has nproved from light perception to 15 100 A great deal of good an be gained from treatment, but the prognosis must be uarded until the fundus can be made out

Dr **H B Young**, Burlington—I have recently seen two ases *One was benefited by potassium iodid, the other was* ot My impression was that the origin of the disease was ncestral

Dr **D S Reynolds**, Louisville—If there is any cause for *disseminated choroiditis other than syphilis, I am entirely* unacquainted with it

Dr **B A Randall**, Philadelphia, Pa —We are generally correct in contrasting clinically the minor conditions of choroidal irritation with those of unmistakable choroiditis that leaves permanent scars, but no absolute pathologic line can be drawn between them

Dr **A E Portman**—Many cases have been reported by Drs Argyle Robertson, Hutchinson and others, believed by them to have no specific connection Research, however, in this line can do no harm

THE OCCURRENCE OF OPTIC NERVE ATROPHY IN GENERAL DISEASE

BY H V WURDEMANN, M D

Director Wisconsin General Hospital and Secretary of the Association
Oculist and Aurist to the Milwaukee Children s Hospital and to the
Milwaukee County Hospital for the Chronic Insane

MILWAUKEE, WIS

Being Report of the Chairman of the Special Committee appointed to report upon "Optic Nerve Atrophy of Obscure Origin" for the Section on Ophthalmology of the American Medical Association, Forty seventh Annual Meeting, held at Atlanta, Ga , May 5–8, 1896

The origin of most cases of optic nerve atrophy is certainly obscure There can be no doubt, when the amblyopia and characteristic disk changes follow traumatism, peripheral disease, or there is positive diagnosis of cerebral disease, or following the continued action of some virus or poison in the system, that is known to affect the optic nerve The occurrence of optic nerve atrophy in general disease always brings with it doubt as to the causative relation The statements of patients are unreliable especially as regards nature, duration and severity of preexisting diseases and an element of doubt is always attached to the relation of such a chronic process as nerve atrophy which may have begun months or years after an apparently well authenticated cause

The atrophy may involve the whole structure of the optic nerve for its whole length, or may be complete in only a portion, it may effect a part of the nerve fibers, in their whole length or only such a portion as the maculo-papillar bundle Signs of degeneration may come on so quickly that the disease may be deemed acute, the majority of cases, however, are characterized by slow changes and do not tend to recovery and hence are truly chronic The latter class shows few signs of inflammation, although I believe, in the beginning that it may be generally possible to demonstrate inflammatory changes at the disk, in the shape of slight haziness and blurring of the nerve head, especially its edges, and of increase in the size, tortuosity and number of its small blood vessels A large number of cases follow high grades of inflammatory conditions of the nerve and retina, such as occur in neuro-retinitis and choked disk

It is difficult to decide whether some cases are due to or simply coincidental with the preceding trauma, local, cerebral, spinal, toxemic or general affection, which may be followed by atrophy of any part of the nerve from the visual centers to the disk, but the result in any case is eventually seen as a wasting away of the nerve elements The disk loses its normal rosy tinge, the circulation is reduced in amount, in advanced cases is marked by a cupping of the nerve end, especially on the temporal side In all cases the first symptom is loss of visual acuity followed by more or less concentric contraction of the visual field, with perhaps defects and disturbances of color perception Where blanching of the macular fibers only appears as in axial or partial atrophy, central or ring scotomata are seen The color of the disk may vary from a pure white, as in primary or simple progressive atrophy, to grayish as is seen after neuritis Bluish or greenish shades commonly appear after spinal lesions and sometimes pigment deposits occur in the nerve Glaucomatous disease results in atrophy of the fibers and here the discoloration is frequently marked

In addition to considering optic nerve atrophy with constitutional and infectious diseases I shall discuss affections of the digestive, respiratory, circulatory, urinary and sexual organs with diseases of the skin and those cases which are supposed to be congenital and those which for want of a sufficient apparent cause will be termed idiopathic

1 *Diseases of the Digestive Organs* —Disordered digestion and assimilation with attendant defective nutrition are factors in many general and local diseases Infectious diseases may leave in their train such conditions of the digestive tract, which act apart from their toxins in producing effects on the trophic centers and nerves I have observed simple white atrophy for which I could give no other cause than chronic catarrhal gastritis and the uric acid diathesis Blindness and subsequent atrophy has been noticed after profuse diarrhea Intestinal hemorrhage has

been followed by white atrophy. In retinitis pigmentosa and hemeralopia secondary atrophy of the optic nerve follows. This condition has been ascribed to co-incident liver disease, but in no case has there been a sufficient warrant for ascription of a definite connection between the two. It is certainly more probable that hereditary syphilis is the cause of these conditions.

2. *Diseases of the Sexual Organs.*—Excessive sexual indulgence and masturbation have been reported as causes of this change in the optic nerve. Amenorrhea and sudden suppression of the menses with vicarious hemorrhage into the nerve sheath is a probable cause of several personally observed and other reported cases. The disturbances attending the menopause in a subject inclined to arterio sclerosis, have developed the condition. Pregnancy may develop a preexisting tendency to eye or general disease. Although uremic blindness is usually temporary, repeated attacks occurring in the same or successive pregnancies have been known to result in permanent atrophy. Nephritis of pregnancy with accompanying, so called albuminuric retinitis has been followed by the same result. Parturition and childbed offer peripheral causes, such as hemorrhage into the nerve sheaths or centers. The mother is exposed to local and general infection and the child to direct injuries which, in the case of the latter, may be the cause of some of the congenital cases. Auto-intoxication from lactation has been reported as a cause of optic neuritis followed by partial atrophy.

3. *Diseases of the Respiratory Organs.*—The adjacent nerve, chiasm or tracts may be implicated in diseases of the sphenoidal sinuses following disease of the nose, causing blindness or diminished vision with defective fields. Optic atrophy has followed pneumonia and repeated operations for empyema.

4. *Diseases of the Circulatory System.*—In anemia and plethora the eye is seldom directly affected, for the amount of blood in the eye may often be the reverse of that in other parts. The quality of the blood, however, is certainly a factor in nutrition of the eye and nerve. Thus, vascular affections may become harmful through the chronicity of their course and produce optic atrophy long after the cure of the original disease. We sometimes see cases of anemia and chlorosis with heart lesions, which may be a sufficient cause for the nerve disease, either through the results of embolism or hemorrhage or through malnutrition. Hemophilia, epistaxis, hematemesis and general hemorrhage have been followed by atrophy.

Arterio-sclerosis, atheroma and fatty degeneration of the blood vessels occur in certain general and specific diseases and are directly responsible for defective nutrition or hemorrhage into the nerve or sheaths, which results in atrophy. Vascular diseases which cause embolism or thrombosis may give rise to atrophic patches in the choroid or the retina with secondary partial degeneration of the optic nerve.

5. *Diseases of the Urinary Organs.*—Twenty per cent. of all cases of Bright's disease suffer from albuminuric retinitis, which, after resolution, will be marked by more or less atrophic changes. Double optic neuritis followed by partial atrophy has resulted from retention of the urine in a case of acute nephritis.

6. *Infectious Diseases.*—Both the acute and chronic infections act mainly upon the blood vessels, which, in many cases, are indirectly changed a long time after the first infection has passed away. Such lesions are of a simple atrophic and not of an inflammatory character and may occur in the brain, spinal cord or peripheral nerves. When the course is acute and the eye is soon affected, inflammatory changes or hemorrhages occur in other parts of the eye as well as in the nerve. Some of these are purely mechanical, as in the case of violent coughing or vomiting. When the course is less acute the virus is expended, apart from the vessels, upon the interstitial connective tissue, while the parenchyma remains healthy or is involved only in the stage of reaction of the interstitial process.

In rheumatism the deficient action of the kidneys and defective elimination of uric acid produce changes in the blood vessels which affect the nutrition of the optic nerve. So also in arthritis deformans, podagra and muscular rheumatism, atrophy may result. These conditions cause glaucomatous disease which eventuates in optic atrophy. Measles and scarlet fever aside from nephritis, typhoid fever, cholera, pertussis, parotitis, dipththeria, beri-beri and pellagra are occasionally responsible for optic nerve atrophy, while influenza is a fruitful source of blindness. Malaria is a cause of atrophy, though some of the cases reported may have been due to quinin. Syphilis is one of the commonest causes of optic nerve disease. It either affects the nerve directly by the lesions it produces in the nerve or its sheaths, in the chiasm or the tracts, in the brain or spinal cord, or by disturbances of nutrition, these conditions give rise to neuritis, retrobulbar neuritis, thrombosis or degenerative changes in the nerve, or indirectly through the changes which occur in tabes and allied diseases resulting from syphilis.

The tertiary stage of syphilis causes interstitial changes in the peripheral nerves including those of sight. Gummata of the brain may produce peculiar defects of the visual fields with atrophy. I have noticed monocular hemorrhage and retinitis followed by optic atrophy in congenital syphilis.

Epidemic and other cerebro spinal meningitis has been followed by atrophy of the nerves of sight.

7. *Constitutional Affections.*—Although we may find atrophy of the optic nerve in some cases of tuberculosis and scrofula and despite the fact that these conditions are extremely common, no proof has yet been adduced that they are capable of causing atrophy in other ways than by affecting the general condition. Diabetes may set up retinitis, neuro-retinitis or retrobulbar neuritis with secondary atrophy of the optic nerve. Exophthalmic goiter, myxedema and leukemia have been accompanied or followed by atrophy of the optic nerves. One of the most constant symptoms of acromegaly and megalocephalia is optic atrophy.

8. *Congenital Optic Nerve Atrophy.*—Many cases of hereditary atrophy have been reported. The blindness usually commences at puberty or during early adult life. The actual exciting causes of the amaurosis may lie in some of the foregoing diseases or in alcohol or other toxins. They are certainly of doubtful origin, although we are inclined to believe that the original cause of some of them is due to anatomic changes in the sphenoid bone which produce pressure on the optic nerve or to the mechanical influence of dilated and calcified vessels which ensue later in life and are associated with certain forms of atrophy in old people.

9. *Diseases of the Skin.*—We may un

stand how diseases of the skin give rise to conjunctival and corneal disease from extension by continuity and similarity of structure A case of neuritis with resultant atrophy has been seen after extensive eruptions on the scalp Erysipelas may affect the optic nerve when attended by orbital cellulitis, with atrophy following Enormous thickening of the chiasm and nerve has been found at the autopsy in a case of elephantiasis

10 *Miscellaneous* —Exposure to cold is a common cause given by patients to almost every affection It is possible that this may be the exciting cause of an acute exacerbation of previously existing disease, which may determine optic atrophy Sunstroke, exposure to continuous heat, light and high altitude or climatic conditions are certainly very rare causes We sometimes see cases of well pronounced atrophy in which in neither the history nor in the examination are we able to find a sufficient, apparent original or exciting cause

Conclusions —Optic nerve atrophy occurs in general diseases usually as a result of direct irritation from their toxins causing inflammation with resultant interstitial changes or through necro-biotic changes in the blood vessels affecting the nutrition of the nerve and retina A certain proportion of cases are due to trauma and to actual lesions which cause pressure on the nerve or interfere with its nutrition through ambolic processes Although many cases are of apparently obscure origin, in the majority it is possible to demonstrate a sufficient exciting cause

Note —This paper is but preliminary to another in which about one hundred case histories will be reported

The thanks of the author are due to Drs Risley, Hotz Hobby, Foucher Wilder Zimmermann Wheelock Gould White Spalding and others who so kindly sent examples from their own observation In the foregoing no authorities are credited for literature see complete paper

TREATMENT OF THE INSANE

Read by title in the Section on State Medicine at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5-8 1896

BY S V CLEVENGER, M D

Alienist and Neurologist Alexian and Michael Reese Hospitals Chicago formerly Medical Superintendent of the Eastern Illinois Hospital for the Insane and Pathologist of the Cook County Insane Asylum author of 'Spinal Concussion ' ' Comparative Physiology and Psychology, ' etc
CHICAGO ILL

Treatment of the insane by our prehistoric ancestry can be inferred from fragmentary early literature and from conditions among existing races that have preserved the ideas and customs of remote periods No precise chronologic statement could be made that would be true for all countries at any particular time, for civilization is a relative matter

In India, a thousand to three hundred years before Christ, the causes of insanity were recorded as due to improper food, overwork, poisons, powerful emotions, etc , deranging the "wind, bile and phlegm," and six kinds of insanity were described, and in attempts at cure chastisement alternated with persuasion and gentleness Elsewhere, at the same time, possession by evil spirits was the generally accepted explanation of insanity, and the afflicted were beaten to rid them of their devils, while priests were presumed to have some power of exorcism

The custom of destroying the weak and defective was very prevalent The early Romans threw their monstrosities from the Tarpeian rock, American savages often abandoned their aged and crippled to the wolves, and promptly destroyed idiots and the otherwise congenitally deformed

Lunatics have been considered by the Mussulmans and some other barbarians and semi-civilized as entitled to special privileges, through a superstitious regard for them, and epilepsy was inconsistently looked upon as both a diabolical and a divine affliction, *morbus sacer*, or sacred sickness, being the term often applied to it The epilepsy of Mohammed added to his religious influence

Egyptian papyri indicate that drunkenness was recognized as a cause of insanity five thousand years ago, senile decay was also described and evil spirits were blamed as causing insanity The Coptic descendant of the Egyptian language has words to express insanity stupor and mental loss

The Bible refers to the feigned dementia of David, Saul's madness and Nebuchadnezzar's mental affliction Herodotus mentions the madness of the Persian king, Cambyses, Sophocles tells of the insane fury of Ajax, and Euripides describes mania and epileptic insanity Plato suggests fines for those who do not properly provide for insane relatives, indicating that such patients were allowed to run at large and were neglected, as was the case in England down to a recent period

Babylonian inscriptions invoked the gods for aid to sufferers from "sickness of the head" Plautus describes senile dementia in a comedy and narrates an instance of madness caused by "black bile Hippocrates, 500 B C , combated the popular idea of epilepsy being a divine disorder and recognized it, as well as mania, melancholia and dementia as due to bodily ailments He prescribed hellebore for insanity Asclepiades sought to induce sleep in the insane by gentle friction At the beginning of the Christian era Celsus advocated "hunger, chains and stripes' for madmen, though there were occasional attempts at cure by music and reading aloud to them Cælius Aurelianus opposed violence to patients, and Galen gave rules for treating insanity as sickness Plutarch describes melancholia of the religious kind, and Horace gave rules for determining the sort of insane who needed interdiction and restraint

It was the custom among Roman ladies to have idiots and imbeciles among their servants, though occasional protests were made against so doing Court jesters were frequently selected from among the deformed or mentally unsound in medieval periods

Early in the world's history organization for other than defensive and offensive purposes was comparatively crude and cruelty abounded on every side Not only were the insane the victims of brutalities to a greater extent than at present, but degeneracy often ran riot among rulers, affording the "insanity of power" mentioned by Italian writers, which raged in connection with epilepsy, imbecility, paranoia and even chronic mania in the imperial families of Rome, Russia, India and other countries, afflicting Julian, Tiberius, Caligula, Claudius, Nero, Heliogabalus, Peter the Great, Ivan the Terrible and Mohammed Toglak, the sultan of India, as well as the founders of the Mohammedan and other sects in Asia and Europe

Through the restraints of his environments and fellows, man is more accustomed to be controlled than he is fitted for the exercise of unlimited power, which favors the development of latent mental and moral imperfections The abominable cruelties perpetrated by some of these insane rulers are equaled only by the sufferings which the insane in all countries and ages have been forced to endure. Probably when merely neglected and permitted to run at large these defectives endured less from the peltings and derision of villagers, with occasional burnings at the stake as witches, than after the commonwealth began to make laws concerning them.

The earliest provision made for the custody of lunatics in England was under the vagrant act of 1744, and the constable of Great Staughton, Huntingdonshire, records an official charge of 8 shillings 6 pence "for watching and whipping a distracted woman." Shakespeare mentions in "Rosalind" the "dark house and the whip" with which madmen were punished.

The sequestration of lunatics as a public necessity had as little reference to the possible cure of such persons as, until recently, the idea that drunkenness was due to a diseased state obtained credence. And the superstitions of the ages found in the gathering together of the insane better opportunities for practicing theories of casting out devils by reducing the patient to extremities through starvation and beatings. Willis, who had charge of the insane George III, advocated fear in the treatment of patients. This royal sufferer's legs were duly blistered and he was dosed with Peruvian bark after the fashion of the day, and the king complained of the severity of his attendant, who is reported at times to have "knocked his majesty as flat as a flounder." Public discussion of this case led to some general amelioration of the insane in England, which was built upon later by Dr. Conolly and the compassionate Earl of Shaftesbury, but not without encountering ignorant opposition, for Conolly and Gardner Hill were denounced by the English clergy for imperiling the community by unchaining lunatics.

Riel among others, described the horrors of German asylums in 1803. Before a parliamentary committee in 1808 it was testified that the insane in Ireland were tied by the arm to a cart and were thus dragged to the asylum, walking the entire distance, however far, and that mortification from tightness of the ligatures caused one in five to lose an arm. The communal and ecclesiastic control of the insane at Gheel, in Belgium, was hideous enough until the State took charge.

Some of the appliances used in restraining and "treating" the insane were the "Belgian" and other cages, wicker baskets, rotary machines, suspended boxes and seats or hanging mats, swings, hollow wheels, the crib, gags and head frames. The douche was used as a means of punishment and sudden plunging into "surprise baths" were in favor at one time to arouse depressed and discourage refractory patients. Most of them, however, were penned up in filthy, close rooms, sometimes of stone with wet floors, freezing in winter and stifling with heat and offensive odors in summer, fed on scanty and coarse food, often sleeping naked on straw and several in one bed. Frequently the poor creatures were devoured by rats if they survived the thirst, hunger and pestilential diseases that carried off many of them. Added to this there was usually brutal supervision. Sometimes convicts were employed to treat them as they pleased, and Esquirol relates how the madmen, goaded by ill-treatment, would watch an opportunity to kill their attendants with their chains.

By very slow degrees the care of the mentally afflicted has been improved. The inertia of governments and the merely temporary influence of exposures with want of general concerted action accounts for much of this slowness. There was fierce opposition roused in 1855 against the investigations in Scotland that were instigated by Miss Dix, and it was by effort out of proportion to results that finally secured a royal commission which occupied two years in examining into and finally reporting upon the cruelties to which the insane were subjected in that country.

In 1788 a Florentine named Vincenzio Chiarugi instituted the renowned asylum of Bonifazio in Italy, as a distinct departure from the inhumanities of the time. Cleanliness, gentle treatment, medical care and the fullest liberty supplanted the universal brutalities in managing the insane. It was ten years later when the chains were struck off the patients at the French Bicêtre through the long pleading of Pinel. He outlined a reform which was improved upon by his successors. Esquirol, in 1818, wrote to the Minister of the Interior: "Nude were the lunatics I saw, covered with rags, stretched on the pavement, a little straw to defend them from the damp cold. I saw them grossly fed, deprived of air to breathe, of water to slake their thirst and of things necessary to life. I saw them committed into the hands of whippers, a prey to their brutality. I saw them in narrow, dirty, fetid receptacles, without light or air, chained in certain dens and as wild beasts are penned in and kept secure." Pinel was suspected by the revolutionists of having a sinister design in asking permission to unchain his lunatics, and a deputy of Robespierre wrote: "Citizen Pinel, to-morrow I come to pay you a visit at the Bicêtre, woe to you if you lodge among your lunatics any enemy of the people."

Passing to our own times we find that an advance has been made toward a *pretense* of care. Formerly it was not necessary to even pretend that humanity was practicable in the management of the insane.

Home treatment of patients is usually difficult or impossible, and as the laws concerning supervision of the insane became more stringent most astounding instances of cruelty and neglect of insane by their relatives were discovered. Imbeciles, idiots and dements were found here and there through the country confined in dismal, small cells, scantily fed and clothed, and their bodily needs otherwise disregarded. On the other hand there are families who are making daily sacrifices in many ways to such unfortunates in their affectionate care.

Small places are not fit for troublesome cases. The long corridors of the State hospitals and the expanse of gardens furnish room for exercise and air, where the privations of a dwelling act prejudicially and compels resort to confinement and mechanical restraint, when all possible and reasonable liberty is everything in the treatment of insanity.

Attendants of the insane as a class are misunderstood and often unjustly blamed for what is most frequently due to the system of management of the institution. Even in the most degraded political asylum several really worthy persons have by some accident managed to be present, but too frequently their lives are made wretched by the perverse element and through their inability to prevent the abuse of patients by others.

In caring for the insane g   as to
be constantly used, for pati   ng
and abusive to an exasperat   s

an all too universal disposition to hold them to account for what they do or say "They are not responsible," is daily mentioned by one kind-hearted attendant to another, and in positions calling for so much self-restraint and forgiveness under extreme provocation it is really surprising how well attendants acquit themselves But helplessness and opportunity are sufficient to tempt the brutes that low-grade politicians appoint to asylums

If political control can be minimized and attendants be secured on their merits and promoted as they deserve for efficient service, salaries should be large enough to induce those possessing more than average ability to enter the service, but where the salary is the only inducement to the ruffians who demand reward for political work it is far better to make the salary low, for a better class of attendants in those politically dominated places is thus secured, from among medical students or other persons of good character who seek temporary means of study

The great strain to which attendants are subjected when on duty makes it but just that they should have reasonable opportunities for relaxation and recreation

If the political teaching prevails that it is not wrong to steal public property, employes can not be expected to be diferent from those over them, and while trustees or a business management may felicitate themselves upon their methods of "addition, division and silence," as conducted in safety and secrecy, their workmen claim also political spoils and extend the system to a practical looting of the place, carrying off everything portable at times At Dunning there were "fence houses" and all-night saloons surrounding the county asylum where blankets clothing of patients, tableware, food etc , were taken from attendants in payment for drink and gambling losses

Great differences exist, due to personal excellence of attendants, as to the treatment patients receive In every institution there are instances of life-long friendships springing up between the recovered patients and those who cared for him or her, and the mere presence of a well-intentioned, considerate attendant has often been sufficient to calm the fury that had been caused by the harshness of others

On the other hand, the greatest cruelties were practiced upon the insane at the county asylum by the criminals who were selected to fill the place of attendants, as appears from the Report of the Board of Public Charities, State of Illinois, 1886, page 119, and years later the asylum was worse than ever, and several murders of patients were brought to light judicially

If the medical superintendent were not hampered by demands of politicians for positions to be filled by unworthy persons the decent care of the insane would be greatly simplified As an example of the selections politicians often make it suffices to state that Peter Kelly, a Chicago policeman, was shot by a burglar and became insane from the neck wound inflicted, the assailant served out his time in the Joliet Penitentiary and was appointed as an attendant at the county asylum and was actually put in charge of the ward within which was Peter Kelly, his victim

Dr Joseph Lalor of the Dublin, Ireland, asylum, founded schools for the insane, and he was also an enthusiast on the subject of keeping the patients employed Farm labor is beneficial to both curable and incurable cases, beside being an economic source of supply to the asylum Almost every conceivable occupation is represented in the best managed institutions, and the daily labor of the patients contributes greatly to their welfare and happiness But there are opportunities for abuse of employment in overworking or unsuitable occupations A contractor at the county asylum was allowed to appropriate the patients' labor, and the warden (who later served a term in the penitentiary for robbery) compelled the insane to hard labor against their inclination A patient died of typhoid fever while digging a trench for the warden and contractor mentioned, both of whom resented any medical interference with their control of the insane

Visitors to insane patients often do much harm unintentionally Friends and relatives exert an irritating effect upon the insane in unexpected ways, and calmness has frequently been succeeded by weeks of disturbance after the visit of a well-meaning relative There are times, which the physicians are prompt to recognize, when the patient is made better by seeing his friends, and they are usually notified to come at once upon such occasions Several thousand visitors and pleasure seekers have been known to throng and race through public asylum grounds, especially on Sundays, and the attendants on such days had their hardest work in controlling the patients who were thus improperly disturbed

Several hundred members of the legislature with ladies, children and friends, "visited for inspection" some of the State institutions, taking possession of the place, converting attendants into nurses for infants, holding a banquet in the dining room of the hospital, drinking the dispensary liquors, rioting through the grounds and actually taunting some of the patients into fury The effects of such a visit were observable for months afterward in many injurious ways A small committee of inspection could accomplish all the legitimate work necessary where a rabble did nothing but harm

Attempts to regulate Sunday visiting at a State institution brought a storm of opposition, as the diversion of travel threatened to break up some saloons in the vicinity in which one of the trustees was interested

No institution of the kind should contain more than 300 insane is the universal declaration of alienists and others experienced in the treatment of these patients, but large and still larger asylums are built, as they afford better and still better opportunities for the management of great amounts of money after the political fashion The impossibility of a medical superintendent overseeing so large a place as the average asylum, with one or two thousand patients, affords a pretext to politicians for putting in a "business agent, ' but invariably the double-headed arrangement proves to be a monstrosity, for no layman, even under honest cooperative endeavor, can possibly be aware of the needs of the patients and the place so well as the medical director The insane are sick, and every moment demand the consideration due to sickness that only a physician can give

Every ounce of supplies purchased, every turn of a wheel has reference to the care of patients, not mere boarders or cattle who require nothing but housing, feeding and grooming When a layman has free control of a hospital he is more than liable to ignore medical requirements, as he knows nothing of them and the medical head is humiliated and common decency is outraged by the necessity of constant appeals to ignorance Even when a steward is under the medical management, the latter is often defeated by intrigues of the former What then is to be expected of divided authority, or, worse than all, the medical under lay supremacy? Imagine a judge being dictated to, by anyone, as to what legal books of reference he should purchase, particularly by a politician who, while preaching "economy " pocketed the public appropriations for legal book purchases Most of the lay superintendents of county asylums are purely business agents of politicians in the worst sense of the term Neglect, abuse and even murder of patients flow from such administration as naturally as foul water from a sewer

It is often the case that the purely professional man is a poor business manager, but that is merely because of his devotion to his work, let the same professional man fully realize that in assuming charge of an institution for the sick that he must become a business man and his professional knowledge is be merely a part of intelligent training as to requirements, and the same ability that made him a good physician will also convert him into the efficient business medical administrator, for special ability is nothing more than general ability There will occur differences among individuals as to whether relinquishment of lifelong habits are possible, and with this in view superintendents should always have had previous hospital experience, but there can never be any excuse on the ground of pretended "lack of executive ability" by medical men for the foisting of brutal, rapacious uneducated politicians into control, however disguised as gentlemen they may be

The ' business manager" in some institutions has claimed the right to make purchases of medicines and very inferior stocks of drugs at high prices are pretty sure to result, against which physicians dare not complain at the cost of falling under politicians' disfavor Inert quinin pills containing a little quassia to impart a bitter taste have been found in such stocks, fluid extracts as valuable as so much cold tea, but billed as Squibb's at his 20 per cent advance over usual prices Calomel which required a teaspoonful to equal ten grains, and other evidences of business enterprise in purchasing abound when the "executive ability" of a layman is placed over professional desire to have pure medicines

At the county asylum the warden refused to buy a few dollars' worth of needed medicines on account of their expense, but the next drug account itemized 48 cases of beer, 10 barrels of whisky, 20,000 cigars, and much wine, brandy and fancy liquors were also covered by the item "sundry drugs " The periodical celebrations of the county commissioners and their friends in the dance-hall and dining-room of the asylum necessitated rapid and constant replenishing of that portion of the dispensary stock Five dollars per capita would have covered the amount of meat eaten by 600 insane at the county asylum, yet in 1884 the bills were $15,763 04, and in 1885 amounted to $18 ,934 11, averaging $26 and $31 per patient, while 9 cents per pound was charged for hogs' heads in a filthy condition, some of which held iron rings in the noses Mike Wasserman, one of the convicted boodle commissioners of unsavory memory, when once shown the iron ring in a pig's snout found in the soup of a patient, remarked "Well, what would you have, gold watches?"

The bookkeeping of a large asylum can be made so elaborate as to be meaningless Voluminous ledgers and auxiliary books and records have been known to be pure shams Requisitions supposed to be sent to the storekeeper by attendants were not approved by supervisors or anyone else, and the storekeeper had every chance of misappropriating goods, and under the loose system of issue no proof could be secured of his guilt Small quantities of butterine issued have been charged up as butter in large quantities, the actual ration of some of the dements consisting in forty grains of butterine, one five-hundredth of a pound of inferior tea and a small plate of corn-meal mush, and patients have fought over their scanty fare, the most helpless being often wholly deprived of food

Sixty per cent of the English asylums are maintained at 8 shillings 7½ pence for county and 9 shillings 7½ pence for borough asylums, which cost includes provisions, medicines, clothing, salaries, wages, furniture, and in some borough asylums, repairs At Leavesdon, in 1887, the weekly cost was 7 shillings 5 pence In Scotland the cost ranged from 5 shillings 10 pence to 10 shillings ¾ pence, the extremes per annum through England and Scotland being $72 80 and $125 58, with an average of 8 shillings 7½ pence per week or $107 64 per year

In 1894 the lowest per capita in the United States was $104 at the Tuscaloosa, Ala , asylum, the Southern per capita average of all institutions being $129 23, the Western $166 58, the Northern $173 60 and Eastern $173 42 The average of fifty-two asylums in the United States being $169 15, which is considerably above the cost of maintenance of the English asylums

While the average cost of American asylum maintenance was about three-fourths greater than in England, at the Chicago asylum the per capita in 1885 reached the sum of $270 39 under county commissioners who were subsequently indicted for conspiracy and fraud The Illinois per capita of that year was $174 21 The succeeding year $243,262 33 was expended for about 700 patients, raising the per capita to $347 51 The total county charity expenditures for 1886 was $906,478 34, at least two-thirds of which must have been misdirected on the safe assumption that the asylum per capita was about thrice what it should have been

During the years of the boodle gang control some $10,000,000 of public funds were disbursed, one saloonkeeper was awarded a contract of $150,000 for covering the court-house with a mixture of clay and paint, the cost of which was about $500 The robbery of the insane asylum fund was a small portion of the political division of spoils In 1886 the poorhouse per capita was $200 and the county hospital $373 57, while in all the public charity departments the greatest privations were experienced by the inmates in spite of the vast sums appropriated "Economy" was the excuse of the politicians for the miserable provision made for the sick and paupers

It is with the greatest difficulty that the expense account of county institutions can be approximated Concealment is the rule and in the words of a county commissioner, "the county expenditures is nobody's business " Collusion among all asylum officers is not to be presumed, for many of them are kept in ignorance of financial matters and can only see results in a general way against which they can not protest

Estimating possibilities in the State institutions, it is practicable for $150,000 to [illegible] a [illegible]ed from

$500,000 biennially appropriated for a single institution, through perquisites of $30,000 to the one who heads the division of offices, sometimes a member of the legislature who has controlled a large number of votes for the State election, one trustee, who acts without salary and merely for the honor of the appointment, by diligently attending to the hospital business can secure $50,000, a less influential trustee can save $20,000 by coöperating with his companion in the matter of auditing accounts, while the one whose vote is not needed can be placated with $5,000 The storekeeper has opportunities to earn $10,000 on his $75 per month salary An industrious business manager can net $25,000, the bookkeeper, through occasional opportunities can add $1,500 to his savings, and $8,500 can be secured by others in various ways from the wastage and shrinkage fields of the place The treasurer is openly known to receive the interest on the asylum funds, though there is no legal provision for so doing Probably $3,000 per annum is thus earned, and if in the meanwhile the State is in need of funds it can readily borrow by paying interest

From $2,000,000 annually appropriated by a State for maintenance of its charitable institutions, one-fourth can be abstracted without the knowledge of the State board of charities or the medical superintendents, and without causing much privation among patients, the different funds affording dissimilar chances for discounts

The "stuffing" of pay rolls is not so likely in the State hospitals, particularly when the pay list is published, but in county and city offices of all kinds great sums have been made by placing fictitious or false names or rates of pay on pay rolls of employes An 1896 instance was unearthed by a civil service commission investigation, conducted by attorney Luther Laflin Mills The clothing account can be profitably manipulated, in county asylums especially At Dunning 100 suits would be issued to a ward full of patients, and the next day the same suits were reissued to another ward The friends of patients incessantly complained that the patients were not wearing the clothing brought to them, and the destructiveness of a few patients was made to do duty as an excuse for the disappearance of hundreds of suits

Fuel purchase in some places enables incredible sums to be charged A very superficial examination would result in astonishing disclosures in this field, unless baffled by the opposition usually raised against exposure of any kind

Trustees are ostensibly selected for their business aptitude, public spirit and philanthropy, they receive no pay, and are presumed to regard the honor of the appointment as sufficient recompense Occasionally it happens, after a political overturn, that prominent political workers, for services in securing votes, are rewarded by such trusteeship appointments, and while it is not invariably the case, it too often happens that a four years' term as trustee enables a poverty stricken politician to blossom out as a banker, real estate owner or man of wealth generally

Combinations are sometimes formed among them in such a way as to control matters, and the resentment of the minority rises to threats at times, with the compromise that ensures silence When an indignant trustee resigns and calls his former comrades hard names, you may rest assured he is not satisfied with his share of the profits A $60 a month clerk has been known to spend his entire time at an asylum while acting as trustee without salary, and the loss of his clerkship was taken quite philosophically One of the sixteen county commissioners who were subsequently indicted under what was known as the "omnibus boodle" finding, neglected his small saloon in Chicago to reside at the county asylum altogether He escaped to Canada too soon in his career to have saved much money An Indiana asylum trustee displayed more "executive ability" than the rest by placing $100,000 of asylum funds in his carpet sack and traveling northward, without the preliminary bother of obtaining percentages for asylum supplies from bribing merchants

All asylum trustees are not dishonest, but the system is sufficient to develop whatever dishonesty may be latent in some, through the opportunities afforded

Under the New York State Care Act of 1890, separate institutions for the chronic insane were abolished as pernicious, and Illinois in 1896 erects just such an institution

The death rate in New York asylums has of late years been rèmarkably decreased by regulations that restricted the chances of political stealing

Dr Carlos F MacDonald, the president of the New York State Commission in Lunacy (*Alienist and Neurologist*, July, 1896) relates that the changed system in that State enabled a saving to the tax payers of $300,000 over the previous year The cost of maintenance for the fiscal year 1892-3 was $216 12, and in 1894 the per capita cost dropped to $184 84, a reduction of $31 28 The supervision of all expenses by a thorough system of scrutinizing public asylum expenditures in a business-like manner cut off nearly $500,000 a year from what formerly went to politicians, and the patients now have some of the remainder

All per capitas in the United States are too high in the aggregate, and the insane could live as well on one half of what is appropriated for them, were the politicians' hands taken out of the treasury

A State board of public charities without pay, except for its secretary, has ostensible supervision of accounts in Illinois, but the members have not the time to spare for anything like careful supervision, and are thwarted in every way possible in attempts to thoroughly understand the expenditures In no one of the biennial reports of this board is there evidence that proper access to Cook County public charity expenditures was afforded the board Immediately before the celebrated "boodle trial," which showed the most reckless plundering of the public funds by the county commissioners, the State board reported that the county accounts were correct

The intriguery, waste, extravagance, plotting, rioting, neglect of duty, insolence of employes, disregard of the needs of patients and of medical care, the "doping" of patients by attendants, and frequent instances of personal abuse, the insufficient cooking of insufficient food, with the thorough "cooking" of statistics and accounts, the high death rate and low recovery rate, the crowding of several violent patients in one room, and multitudes of other discreditable affairs, must be witnessed to understand how deep-rooted and arrogant a hold the political spoils system has upon the country

And there would be no bribed were there no bribers The merchants who divide public plunder with politicians, and the citizens who look complacently on, are equally guilty

A physician seeking an appointment to insane asylum service asked a veteran alienist what steps were necessary, and was advised in all seriousness to make the acquaintance of the nearest saloon-keeper

The number of gamblers and liquor sellers who hold offices of all kinds in connection with public charity disbursements indicates the influences at work in American politics When surprise is expressed that such selections should be made, it is claimed that such persons are as honest, capable and deserving as merchants and board of trade dealers, many of whom evade tax paying and seek nefariously profitable combinations with politicians to furnish supplies to asylums, hospitals and poorhouses

The fact remains, however, that there is nothing in the occupations of the liquor dealer and gambler that specially fits them for caring for the public insane and their funds, beyond the mere superior ability to control such appointments afforded by the faulty primary election laws, which legislators would speedily remedy, were it not that their own places would be jeopardized by such changes

But asylum management by such classes is merely a legitimate outcome of the general spoils system operation the helplessness of the sick and insane affording the best opportunities for brutality and rapacity The privations, sufferings and frequent murders of insane patients are strictly logical outcomes of the pernicious system which fills our legislatures, State, county and city offices with gamblers and saloon-keepers, who swagger about in vulgar jewelry and attire, openly congratulating one another upon some recent success in prostituting public and private interests All such matters are familiar to citizens who have the power to make reformations, but do not intelligently combine to make them

Reports of the State Board of Public Charities for Illinois are filled with accounts of the insane in various counties being treated more as animals than as men and women, neglected, abused, chained, locked up in nakedness and filth, no medical or personal attendance, packed in rooms too small for their numbers, with poor ventilation and foul odors, no separation of the sexes, insufficient food, and myriad other such matters are officially mentioned in these reports to the governor and legislature, without influencing the least improvement

The charges sustained in the 1886 investigation of the Cook County asylum were

1 Cruelly insufficient provision for the insane in the county asylum in all respects, when more than ample funds are alleged to have been used by the management of said asylum for the care of the insane

2 Abuse of said insane by said management, said abuse being direct and indirect, by personal violence and neglect

Subsequent to this report to the governor, a county court investigation on the petition of Julia Willard May 13, 1889, was made in which witnesses detailed murders and abuse of patients, their starvation and the brutal nature of the management Patients were made to work for the profit of attendants, their clothing was stolen and sold to saloon-keepers, fighting, rioting feasting and drunkenness of politicians were narrated, with no apparent difference in the conditions since the State board report of 1878, except in enlarged opportunities for brutality In that document the county farm was characterized as full of instances of neglect and ill treatment and that "party politics trading votes and speculating" contributed the chief employment of employes

After the 1889 investigation it was considered safer to give no physician an opportunity to bring matters to light, so a lay warden hires the doctors and keeps them under sufficient control to prevent complaints getting to the public

In 1895, as a sample of many instances, two attendants were on trial in Chicago for kicking a patient to death, an "investigation" was made by the commissioners, who duly whitewashed themselves, and by publishing hundreds of columns of newspaper interviews, and vaporings generally, managed to confuse everyone and tire out the public A New York legislative inquiry into the killing of a patient came to nothing through the report of the committee being stolen

Physicians alone are competent to understand the real wrongs of asylums and even they must reside the greater part of a year in such places before they can fathom the real condition of things, which every ingenuity of political intriguery is invoked to conceal

A favorite resource of politicians when attacked for malfeasance or inhuman violation of trust is in diverting public attention from themselves by personal onslaughts made upon their accuser

Nothing seemingly could be further apart than discussions of gambling and the care of the insane, but the most amazing incongruities are seen in the results of political control of offices The successful manager of politics, "the boss of the machine" in a great city, is often the head of a large gambling resort with a saloon and other immoral accompaniments attached, affording rendezvous for his lieutenants in plundering schemes These "bosses" are great organizers, and exert as complete control over primaries, nominations, elections and office conferring, as though they actually owned the State and its revenues Adepts in manipulating election machinery and playing upon the passions, ignorances, and prejudices of the populace, they have defied attempts at their overthrow and continue to divide municipal and other governmental funds and places among themselves Opposition is crushed in every way by corruption, or discomfiture of whoever is rash enough to attempt reform in a practical way, even to the destruction of individuals Windy addresses on reform measures do not disturb them in the least, they can even make such demonstrations themselves, and in the name of reform increase their power for evil It is when actual interference with their robberies are made whether through interposition in behalf of the sick, insane and paupers whose funds they control, or otherwise, that the hand of the "gang" falls heaviest, and the motives and character of the reformer are assailed Nor is their hesitation over a mere matter of assassinating too troublesome an opponent Political murders have been numerous and successfully concealed, the party who makes exposures is adroitly made to appear in the wrong so as to alienate public sympathy from him if his murder comes to light

In the *Chicago Inter Ocean*, Nov 4, 1884, appeared an appeal from a physician at the county asylum stating the atrocities there and asking "all respectable men to be sure that the county commissioners for whom they voted owed no allegiance to gamblers and thieves'

The doctor was promptly shot at and several other attempts were made upon his life and a [illegible] kept up the fight ten years he was finally pronounced to be insane by politicians in general, and certainly from the standpoint of a community which condones robbery of the helpless, the one who refuses opportunities to steal from them must be out of his environment and practically a crank

The mental construction of most of these politicians is such that they can not conceive of mere professional devotion and enthusiasm A physician who would lay claim to being actuated by a desire to scientifically advance humane measures is looked upon as a brother hypocrite and demagogue Honesty is inconceivable except as defective intelligence The refraining from stealing public funds is considered as mere want of smartness enough to know how to do so

It often befalls that an ousted administration busies itself in inventing occasions for spitework with a view to possible restoration to power, so it is not all accusations against the ins by the outs that can be believed

Deaths of patients by violence afford chances, about election periods, for exposures In such investigations the mode of appointment of all officers and employes should be inquired into as affording ideas of the animus and discipline of the place The incentives of charges and the inevitable counter charges need deep probing, as well as does the construction of the investigating body, its interest in the investigation and liability to bring out the truth or cover it up Deposed administrations have been active in arraigning their successors for real or imaginary misdeeds, and upon rare occasions some one has instituted charges from genuine reform motives, but even these reformers are apt to be jealous of one another and instead of supporting, detract from and disparage each other's efforts

Brutal natures are common enough and it is not remarkable that many of their possessors find their way into asylums as attendants in reward for services performed at the polls for those who appointed them When a murder occurs at an asylum the first question should be *Who appointed the murderer* to his position? and full light should be thrown upon the character of the office giver, to disclose the entire responsibility for the commission of the crime

These weakest and most helpless of humanity are not only liable to be neglected through their filthiness, repulsiveness and burdensomeness but their irresponsible aggressiveness has often aroused the brutal retaliation of the none too patient or considerate savage, who, all too often, happened to be in charge

The influence of the saloon-keeper and gambler in placing these characters where they can safely exercise their low instincts, is easily seen Many liquor dealers and gamblers are as they claim to be, as good as many in other occupations that are regarded more respectable, but from their numbers in official life it would seem that they are considered to be even better

When the liquor business is responsible for so vast an amount of crime, insanity and pauperism, does it not seem cruel that liquor dealers should thus be permitted to chase their victims to the grave?

A phase of the wrongs endured by the insane occurs in the blunted conscience of the people in accepting the misappropriation of public funds as a matter of course and even furthering by their votes a determination of which particular band of plunderers shall have charge of the spoils

The merchant who connives with political spoilsmen to sell inferior materials at extravagant prices to public institutions may carouse with the business agent of an asylum and both find happiness in their divided gains, and the thought that life, health, sanity, has been taken from patients through depriving them of what was intended for their care, apparently does not disturb their commercial minds, but the physician who sees patients dying from drinking sour milk and eating rotten meat and vegetables, and from the want of a few simple remedies, or from insufficient warmth because the clothing and fuel accounts had been manipulated with political "executive ability,' the physician who witnesses such things sees clearly who is to blame for the privations, deaths and horrors all about him, while observing the flashy dress and jewelry of the vulgar feasting politicians who have divided almost openly the money lavishly appropriated by the people for maintenance of the unfortunates

The cohesion of the spoils system in its immense ramifications is almost incredible Its beneficiaries surround public hospitals and branch out into commercial and social life in all directions The demagogue relies upon the true condition of things not being understood by the people at large

All the asylums of America are not badly managed, but the present political system does not encourage humane care of the unfortunates An occasional hospital for the insane is well managed in spite of the prevalent bad system, but there is constant danger of a political change driving out the honest and capable from such places

With civil service reform there should be the greatest publicity demanded for all asylum affairs A visiting staff of specialists should be appointed in spite of the fears of some trustees that the world would thus be too readily informed of asylum shortcomings There should be strict scrutiny of the accounts and a check system adopted that would discourage dishonesty Banks overhaul the books of their clerks and railways multiply checks upon their agents, but with all such precautions the ordinary mercantile and manufacturing organization is occasionally robbed Were the defective accounting system in use in State and county affairs to be allowed by all business men and private corporations failures and industrial wreckage would be universal

Civil service laws properly enforced would be directly instrumental in restoring thousands of the insane to sanity, who, under the present faulty system, are doomed, and further murders of patients by politically appointed brutes would cease When the politicians' profits were reduced by $30 per capita in New York State the death rate in asylums fell greatly and the recovery rate rose

Reforms, as well as institutions, evolve and a more scientific treatment of the insane will come with other advances in the world's affairs But, for the present, we can look for no radical improvements in asylum matters until civil service rules are firmly established therein, which can scarcely be hoped for until the primary election methods admit of honest candidates being secured for all public offices, an achievement which means no more or less than the destruction of the power for evil now defiantly exercised by the gambler and dram-seller

Herbert Spencer says "Any system that confers the rewards for merit upon the undeserving is demoralizing and destructive of social advance," and, "though all efforts for reform are out of proportion to the results, the reformer may take comfort in the knowledge that the little that is accomplished will endure

PERTUSSIS AS A NEUROSIS

Read in the Section on Diseases of Children at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga May 5 8 1896

BY S J RADCLIFFE, A M , M D

MEMBER AMERICAN MEDICAL ASSOCIATION MEDICAL ASSOCIATION, D C , BRITISH MEDICAL ASSOCIATION ETC

WASHINGTON, D C

The pathology of pertussis has long been in doubt this is well shown by its varied and uncertain therapeutics The definition of the malady is usually based upon its most prominent symptoms—the characteristic paroxysmal cough and consecutive whoop The cause of this characteristic cough and whoop has never been positively located It is said by some to be a local irritation involving the pharyngo-laryngeal space, set up by some external influence, possibly bacterial, some, that in addition the morbid irritant is absorbed through the lymphatics and blood vessels and produce a systemic febrile state, and some that it is a vague commingling of various elements, local and general, physical and nervous, and still others that its phenomena are entirely reflex There is no doubt regarding its infectious nature, but the peculiar mode of this infection is still veiled in uncertainty It may be from exhalations from the vomited matter or expectorations, the breath, the cutaneous surface, or from all

Whooping cough may be, or may not be of bacterial origin It is not yet proven that it is Certainly no bacillus of pertussis has yet been isolated, and therefore no diagnosis can be based upon a bacillus as a factor in the etiology of the disease

Negatively, and practically, no treatment of a purely bacterial nature has been of any avail Whatever benefit that has been derived from germicides has been by abtunding the terminal branches of the nerves supplying the parts involved, or the parts treated, and have only a local effect, without reaching the source of the nerve energy, its prominent feature

On the other hand, the only remedies beneficially affecting the disease are those that have been considered of a constitutional nature, those that have been directed to the nervous element upon which it is believed to be grounded

The subjects of whooping cough are notably those coming from neurotic families They have descended on one side or the other, or sometimes from both of the parental lines, from generation to generation, from neurotic ancestry, through children and children's children, the concentration varying in individual cases

By careful inquiry it will be found that full 75 per cent of the subjects of this trouble are neurotics in the more or less strict sense of the term, by heredity especially, or it may be by occasionally from acquired habit, and when we consider that as many or more escape the disease than contract it, more are naturally immune than susceptible to it, this view of the subject comes out in strong relief and merits our closest attention No stronger proof is necessary to negative its local origin, or illustrate the resisting power inherent in those exposed to its attacks Those who escape are made of different stuff, but those attacked exhibit the nervous characteristics and conditions of typical neurotics in every phase of life—are easily alarmed, are easily depressed, or impressed for good or ill, are easily moved to tears or excited to anger, their sleep is most always disturbed, they suffer from enuresis, impaired or arrested digestion from shock or fright, are easily agitated and prone to convulsions, which are often produced by very slight causes

If pulmonary symptoms are associated with the disorder, death is apt to occur from interference with the respiratory act, through the dominating nervous element It may cause, during a paroxysm, inhibitory spasm, and, compressing the chest walls, induce asphyxial convulsions and death, or by violent action of the heart muscles increase the hyperemia, overfullness, congestion, or cause the complete arrest of the pulmonary circulation, and by sequence the respiration, and death by apnea

Another very important feature of the disease is the possibility that it is sometimes associated with or may lead to glycosuria It is contended at present that this reference is merely one of suspicion rather than one of fact, yet if we survey the whole field of investigation, and the peculiar symptoms of some of the cases we have had under treatment, where the issues were not plainly developed, our suspicions may be more than verified, by a close comparison of the results of such cases with those symptoms referable to glycosuria It certainly does not conflict with the theory of Pavy, that it (glycosuria) is due to want of assimilation, for want of assimilation is due to nervous influences

This feature of the malady has been very largely neglected, overlooked or possibly ignored as of little utility in the examination of cases presented for treatment But you will be surprised to find, if careful and proper examination or inquiry is made, how frequently glycosuria is present in given cases, especially in the severer types of the disease It is not claimed that this condition is constant or permanent It may be transient, and frequently a very delicate test is required to detect it Though the literature of the subject is at present meager, indeed there is none to be relied on, the indications are so apparent that it may be confidently suggested that investigation on this line would lead to profitable and important results

I doubt if one physician in a hundred has had his attention called to this particular aspect of the matter, or if he thinks it worth while to examine the urine of a child under his care, suffering from pertussis He usually takes it for granted that it is a child's disease, has its period of incubation, onset, acme and decline, and watches to see it pass from one condition to the other rather as an interesting pathologic process, than as a disease to be combatted at every step, from center to periphery He is therefore apt or inclined to ignore or disregard all symptoms except those in sight, and limit his therapeutics to the local manifestations, as if they were all of the affection

We do wrong if, in framing our diagnosis, we leave out of view other organs which may be involved, either primarily, or in the course of the disease, especially such vital organs as the kidneys and their function and products, if we fail to discover or decide as to the appearance of sugar in the urine, and its possible occasion of diabetic conditions, as coma, dyspnea, or pulmonary edema, which are generally looked upon as the result of the inflammatory process

Glycosuric phenomena in whooping [illegible] ugh are usually slight and as a gen [illegible] ng [illegible] ver unimportant part in the complications, or, I might say, in the development of the affection, and on that account may be easily overlooked It is usually temporary, as desquamative nephritis is in scarlatina Yet that it may and does occur to a greater or less extent, this is quite sufficient, as said, to emphasize the suggestion and point attention to it, that we may in the future properly consider its probable immediate or remote tendencies and results

Glycosuria is not properly a complication any more than endo- or peri-carditis are complications in inflammatory or articular rheumatism, or, as now taught, rheumatic fever It is a part of the disease, as nephritis in scarlet fever, and pulmonary extension in pertussis and measles, and originates from the same cause, so that in treating a case of whooping cough, it is well to have in mind all the symptomatic manifestations which may be developed in its course—those that are so far well known and appreciated, as well as the possibilities of some others, not perhaps in the category of direct symptoms, but which may be elicited by careful inquiry pursued in the right direction

It may be, therefore, worthy of renewed emphasis that, if glycosuria is eminently and correctly of nervous origin, affecting primarily the nerve cell and its proliferations, no discussion of pertussis with this accompanying symptom of glycosuria can be complete without including the nervous element, at least, as one of its factors

Another consideration worthy of notice is in regard to its therapeutics, that is, that all the best remedies or treatments heretofore instituted for the relief of pertussis, have been those known to have beneficial influence in all diseases of a nervous type, as neurasthenia, hysteria and the like The remedies, therefore, that do the most good are those that are directed to this end, and the nearer we come to correcting the condition at the seat of action, the nervous centers, whether it be from impaired nutrition, imperfect cell proliferation, antagonism of nerve elements or forces, or retrograde metamorphosis, the nearer we will come to perfecting our therapeutics of pertussis

Those therapeutic agents recognized as anti-spasmodics are the ones mostly relied on in treatment and management of pertussis—all those medicinal agents which act primarily on the nervous system, either immediately or remotely, that deaden the sensibilities, have an inhibitory and quieting effect either locally or generally Local applications relieve, not by destroying germs, but by lessening the irritation and distress of the sensitive parts They have no continued or permanent effect upon the course of the affection, they only temporarily obtund the sensible terminal nervous filamants distributed to the immediate seat of the mucosa to which they are applied They constringe the capillaries, lessen the blood supply, quiet the irritation, diminish the tendency to paroxysmal cough to closure of the glottis, and the characteristic whoop So soon as the local effects wear off the symptoms and paroxysms are the same as before Local treatment can only have a tentative result, unless persisted in without interruption during quickly repeated intervals Only permanent benefit can proceed, and cure result from constitutional treatment

It would be useless and profit but little to enumerate all the remedies prescribed in the treatment of pertussis there are legions of them It will suffice to mention a few of the most recent and popular, or those which seem to have given the best results, namely, bromoform by inhalation, antispasmin, narcein sodium, and sodium salicylate one-sixth to one-fourth grain three or four times daily, phenyl-glycollate of antipyrin, formaldehyd, quinin in large doses, cocain in doses of one-sixth to one-third grain three times daily, and vaccination, which is said to have no effect on those who have been vaccinated Some others are still employed, as antipyrin in laurel water, belladonna atropia, potassium and sodium bromid in decided doses, assefetida, valerianate of ammonium, valerian, infusion of red clover blossom, and chestnut leaves and extract Most of these are administered internally and have a general effect Some are applied locally for immediate results It is agreed they are all of about the same nature, and we have the same object in view in their employment Those that have a constitutional bearing reach the nervous centers, and indirectly medicate locally through the blood current and the nerve supply, and by this means set up an equilibrium or healthy action throughout the system

Spraying the throat and fauces with cocain, antipyrin, potassium, bromid, carbolic acid and the like, aid materially in the treatment, but as said, have only a temporary action, and are not relied on as would be the case if the disease was simply and only of local or bacillary origin Spraying with peroxid of hydrogen, as recommended, could hardly be placed on the list of successful remedies, unless there were pus germs present Spending time in a gas house, at one time in vogue has been abandoned as not favorably affecting the disorder

The main point to have before us in the treatment of pertussis is the general health of the patient This will be most undoubtedly aided, and the cure facilitated, by the patient living as much as possible in pure, open air, by diversions of any kind, and by all means that have a tendency to elevate the standard of health

The object of this paper is more suggestive than argumentative, with no pretense to completeness, and with no effort at detail Its symptomatology, and course and deviation from a typical standard, are too well known to be rehearsed, and statistic information is too uncertain a quantity to be of any relative value

SPINAL INJURIES IN INFANTS

Read in the Section on Diseases of Children, at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Georgia May 5 8 1896

BY JAMES PORTER FISKE, M D
Instructor in Orthopedic Surgery New York Post Graduate College and Hospital Assistant Surgeon Roosevelt Hospital, O P D Attending Physician Children s Department Northwestern Dispensary New York

The subject of spinal injuries in infants is presented to you in order that a discussion by this body of these injuries will determine their relation to the faulty development of the spine in the young, and to determine the relation between trauma and spinal caries

The "traumatic spine" may be defined as any injury to the spinal column Injuries to the spine in the very young are not infrequent, though the great majority of such injuries are slight A simple sprain, muscular or bony contusion, sometimes combined with slight shock, is the usual condition following a slight fall as from a cot or sofa Again a very slight fall or sudden contact with a sharp corner of an object, may produce a true fracture of the spine, usually a fracture of a spinous process If a child falls and strikes sideways we may have a green-stick fracture of one or more ribs with twisting of the bodies of the vertebræ, presenting a clinic picture of "acute rotato-lateral curvature" or scoliosis

While many of these injuries are more or less quickly recovered from, a certain proportion will continue to give symptoms of pain, irritability and malaise A slight jar or wrench may so injure ligamentous structures that symptoms persist for a long period of time, both in adults and children, and such injuries in children may be an etiologic factor as regards the faulty development frequently seen in this region, as in curvature of the spine To the surgeon who persists in making an exact diagnosis, these cases are trying and unsatisfactory, as every injury to the spine, whether severe or slight, must of necessity be somewhat obscure The name "traumatic spine" is particularly applicable, as it is frequently impossible to classify spinal injuries as sprains, muscular contusions, rupture of ligaments or even fracture, unless the case reaches the operating table or the autopsy room

The results of an injury, mild or severe, to the spinal column can never be foretold, but to the rapidly growing infant such an injury may be most disastrous We obtain a history of traumatism in about 50 per cent of Pott's disease, and when we remember that many children apparently in perfect health are the offspring of tuberculous parents, and that such a child has an innate susceptibility for tuberculosis, or more probably has a latent tuberculosis waiting simply for a traumatism at a suitable site before firing up—these considerations should lead us to treat such cases not by observation, as is so frequently done, but by fixation and protection A previous injury is often, I believe, the predisposing factor in the production of spinal caries

Though it is not generally recognized, I believe that traumatism is an important etiologic factor in certain cases of rotato-lateral curvature, and if we could obtain a clear early history, many so-called idiopathic scolioses in children could be shown to follow the traumatic spine Unilateral muscular rigidity, an attempt by the patient to assume the position of greatest ease, a slight bending of one or more ribs, are in themselves sufficient to stimulate a faulty development of the spine in the rapidly growing infant

The examination of an infant suffering from a supposed traumatism of the spine should be as though we were trying to detect early Pott's disease The child is undressed and the posture noted, placed on the table face downward, and spine examined to detect any point of tenderness, ribs each side examined to detect any contusion or bending, feet and pelvis carefully raised to note any rigidity or diminished flexion Pain on pressure, rigidity of the spine and increased irritability of the patient, point to the diagnosis of "traumatic spine," and as such demands treatment by fixation and protection

The necessary fixation and protection in infants is most readily, efficiently and cheaply obtained by a starch-jacket It gives absolutely no discomfort, is not heavy, and it can be applied by any one in a few minutes The material used is wide [illegible] starched bandage about four inches wide of the infant is enveloped in seamless shirting from the axilla to well below the pelvis The starched bandages, after being soaked in water, should be squeezed as dry as possible and then applied The starch-jacket may be applied by the hammock method and should be in the more serious injuries, but as a rule I have extension and counter-extension made by having the child held in the horizontal position, face downward, one assistant making traction at the axilla, a second pulling the thighs at the great trochanters Every jacket should extend from the axilla down to the great trochanters After a sufficient thickness of the starch bandage has been applied, the ends of the seamless shirting are turned toward and over the jacket, thus insuring a smooth and soft border to the jacket The child is now lowered on a soft pillow and the jacket allowed to set It will take some time for the starch bandages to harden, but as a rule the child will rest quietly for a few hours The starch-jacket is quite elastic, firm and considerably tighter than plaster of paris, and is admirably adapted to the traumatic spine in infants As a matter of cleanliness, and for the proper care of the skin, the starch-jacket should be removed at the end of a week, and if indicated another applied, though I have kept one continuously applied for three weeks This jacket is not to be cut down the front, but is intended to stay on as applied

The following case is reported as it represents some of the points brought out in these notes

W , age 26 months, traumatic spine, green stick fracture of fifth and sixth ribs, near the angle, acute scoliosis, fine healthy boy, fell from nurse's arms First saw case on third day of injury Pain and swelling over and to the left of spine over fifth to seventh ribs Careful examination revealed a green stick fracture of two ribs in this region, as well as a contusion to the spine The child in assuming the position of greatest ease, showed a lateral curvature The child was held in horizontal position, considerable extension made, and a starch jacket applied Before application of the jacket the child was in constant pain and distress, after application the child was very quiet The treatment was continued for six weeks At the end of this period all symptoms had disappeared, but at the site of fracture of the ribs some thickening remained The mother wrote me some months later, stating that the child was well in every respect Sufficient extension was made in this case, so that the spine was absolutely straight before application of the jacket

I shall refrain from reporting any other cases as I expect later to exhibit some statistic tables and these notes are presented to you in this form simply as a preliminary to your discussion

In speaking of the prognosis of any injury, several factors are of importance in determining the probable outcome The condition of the child before the injury, the existence of a cachexia a possible latent strumous diathesis, the hygienic surroundings, are in themselves sufficient to turn the chances in one direction or another, whether we shall have an early recovery or a tedious and prolonged convalescence

The relation between injuries and tubercular processes in joints is of great interest Modern pathology, coupled with careful clinic observation, seems to have established pretty thoroughly that many tubercular processes have their birth in a previous traumatism, it being assumed that a tubercular taint was a concomitant condition The [illegible] between prolonged muscular spasm or irritab[illegible] ing a traumatism [illegible] elopm[illegible] ne [illegible] the rapi[illegible] h[illegible] d to [illegible] af ing rule Any injury to the spine in an infant which requires treatment, requires the starch-jacket Lotions should never be countenanced until the symptoms have subsided by the proper use of fixation and protection

ANGIO-NEUROTIC EDEMA

Read in the Section on Neurology and Medical Jurisprudence at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga May 5-8 1896

L HARRISON METTLER, A M , M D
CHICAGO ILL

Though the pathology of angio-neurotic edema is still a mere theory and its treatment a source of continual disappointment, the affection itself is of sufficient importance and its occurrence of sufficient frequency to warrant further study In the *American Journal of Medical Sciences* for December 1892, is an account of the disease, by Collins of New York, which is the most complete of the more recent descriptions Dr Collins' paper is based upon some seventy-five cases gathered from literature and personal observation, to which I can add two more, one having been under my care for about two years The history of this case is as follows

A married woman, 64 years of age, white, the mother of one child living I was consulted by her in July, 1893 Her family history revealed nothing of special note Her own general health had always been fairly good except for a certain nervousness and mental depression brought on by financial losses and worry The climacteric had come and gone without producing unusual distress She was not naturally a neurotic, though her nervous organization was an active one There were no cardiac or pulmonary manifestations The special senses were all unaffected There was no pelvic trouble, no signs of disease of any of the abdominal organs Urinary analysis revealed nothing abnormal And yet in spite of all this negative testimony, for a year or more before I saw her, she had had frequent peculiar attacks of dyspnea, "distress" in the stomach, followed by violent eructations of gas, cyanosis of the extremities, chilliness, great mental anxiety and a horrible fear of sudden dissolution These attacks would appear without the slightest premonition Day and night were alike favorable to them, though the majority of them came on toward early morning So often did they awaken her out of sleep toward daybreak that she dreaded going to bed, and tried the expedient of having her husband arouse her if he were awake at about the time they usually came on Conjointly with these spells appeared sometimes, large, circumscribed, edematous spots in various parts of the body, mostly on the arms and legs, occasionally on the face and epigastrium They resembled giant hives, itched slightly, caused no pain or other sensation than that of slight tension, were raised above the surrounding skin and were of the same color, pitted feebly upon pressure, and were devoid of all signs of an inflammatory nature Sometimes they would disappear from one part of the body to reappear a few hours later at another They have lasted at times from several hours to several days Their disappearance was generally as abrupt as their appearance Singularly enough when these edematous swellings would appear, the abdominal distress and depression of spirits seemed to be somewhat relieved, and later on the patient would walk violently up and down the floor or pass into another room with a different temperature, in the hope of provoking the swellings and thus ameliorating the nervous distress of the attack I have seen her try this several times and though I am at a loss for an explanation, I have been an eye-witness of the relief striven for When the edematous spots had finally vanished and the attack had come to an end, the patient would seem to be almost overcome with extreme exhaustion She would sigh heavily and lie for a long time perfectly motionless Even conversation seemed to be an effort and if left alone she would soon fall into a sound slumber During this period of exhaustion I could not detect any actual difference in the number or strength of respirations or heart beats The patient constantly denied all auræ such as globus hystericus, etc

For her trouble the woman had consulted a number of physicians in the United States and in Canada, had received many opinions, but had never been afforded any permanent benefit Her appetite was good, her tongue clean, her bowels regular There were no indications of gastric catarrh She was a sound sleeper and not much of a dreamer, when she did dream, however, her dreams were decidedly of the distressing, morbid sort Latterly she became very melancholy and much depressed in spirit, especially about the apparent incurability of her disease She suffered no paresthesia save the slight itching of the edematous enlargements There was no spinal tenderness no abnormality of any of the reflexes After one of her attacks there would be an abundant discharge of urine Under my direction she patiently and faithfully tried a long list of nervins, antispasmodics, general tonics, and methods of general treatment such as electricity, hydrotherapy, etc There was no permanent benefit from anything A change of environment and a short trip into the country seemed several times to keep off the attacks for awhile Of all the drugs and chemicals tried, salol and the salicylates, especially the salicylate of soda, appeared to lessen the number and shorten the duration of the attacks While taking these remedies the spells only came on in the morning and lasted but a few hours Though the most effective of all the remedies used, even these ultimately lost their power

Recognizing the hysteric semblance of the trouble I informed the husband of the same and we tried every possible means to divert the patient's mind from herself, such as forcing her into a regular occupation and congenial companionship For a time this promised a happy result, the patient being for awhile less melancholy and depressed, but ere long we were discouraged to see a return of the old attacks, especially the shortness of breath, the gastric distress and the occasional swelling about the feet, hands and chest I warned the family of the possibility of a fatal suffocation from sudden edema of the glottis By and by the attacks became so frequent that the woman refused to lie down at all at night but insisted upon sleeping in a chair At the same time the most careful examination showed no disease of the heart or of the kidneys The patella reflexes seemed to be slightly diminished She complained of much weakness, coughed a trifle without expectoration, said her throat was very dry and exhibited a flushed countenance and red tongue She revived and for several weeks seemed almost well again On Oct 12, 1894, she became much excited from some unknown cause The pulse rose to 100, the temperature remained at normal

Respirations were rapid and shallow There was loud complaining of distress or fullness in the stomach She paced the floor vigorously to bring on, as she said, "one of her old spells," as they at least gave her relief from the nervous distress At odd moments she would try to remove a ring which she supposed was on her finger or to brush invisible objects out of her lap, thus revealing slight visual hallucinations On Nov 29, 1894, I learned that the woman had been seized one night with one of her old attacks and had died of suffocation before the physician who was summoned in the neighborhood was able to do anything There was no autopsy I think the diagnosis of angio-neurotic edema was perfectly justifiable in this case

Angio-neurotic edema, first definitely described by Quincke and his pupil, Dinkelacker, is chiefly remarkable for the circumscribed swellings that appear on the face, neck and extremities, without apparent cause or previous warning For this reason it has sometimes been called *periodic swelling, urticaria tuberosa, giant swelling* There is almost always present gastro-intestinal disturbance, which is probably of an edematous nature like that of the exterior of the body The mucous membrane of the larynx may be the seat of the sudden edema and so cause an alarming dyspnea or even death by suffocation

The etiology of the disease takes cognizance of the early adult age of the patient, its more common occurrence in the male sex, the occupations which tend to excessive fatigue of mind and body, and a certain natural or acquired neurotic state of the constitution Heredity seems to play a not unimportant rôle as shown by the surprising series of cases, all in one family reported by Osler In five generations of this family twenty individuals were the victims Krieger's[1] case was a young man 25 years of age, whose mother was similarly affected Cold and traumatism are frequent exciting causes of the attacks The former in conjunction with lowered vitality, may explain to a certain extent why, as in my own case, the trouble is so prone to appear toward the early morning before the patient awakens Unusual muscular exercise will sometimes precipitate an attack I have seen a hard day's shopping, the patient passing from one store to another through the cold wintry air and climbing flights of stairs, do it

Jamieson's case, reported by Collins, affords a good picture of the symptom-group presented by my own The patient would be perfectly well apparently, and perhaps remain indoors all day Then going out into the open air toward evening, or taking a longer walk than usual, she would experience, without any premonition, a sudden attack of dyspnea, which would frighten and completely unnerve her Her extremities would become cold, the perspiration cease, a slight cough arise and a feeling come on as though the stomach were suddenly distended Generally these symptoms would be quickly followed by the characteristic edematous enlargements upon the arms and face In a few hours the attack would pass off as abruptly as it came, leaving the patient completely exhausted The disease is often associated with hysteria, if indeed it is not itself a hysteric manifestation For a long time I regarded my case as one of pure hysteria, for many of the usual stigmata were present In some cases, as in the first one reported by Collins, hysteric attacks preceded for some years the outbreaks of the edematous trouble Irregularities of the menstrual function seem to perform as much a part in the disease under consideration as they do in true hysteria Collins, Lewin and Quincke cite instances in which the onset and disappearance of the migratory edematous swellings bore a certain relationship to menstruation Amenorrhea was sometimes accompanied by a monthly swelling of the ankles, lips or eyelids

The diagnosis of angio-neurotic edema is not difficult if the characteristic symptoms are present These symptoms are especially the local swelling of the skin, the gastro-intestinal disturbance and the nervous depression The circumscribed edema of the skin is to be differentiated in this disease by the abruptness of its onset, its brief duration and its rapid disappearance Any part of the body may become its site, especially the face and extremities, and in a migratory sort of a way, it may vanish from one part to quickly reappear at another There may or may not be itching It is strictly non-inflammatory, is always more or less sharply circumscribed and sometimes is of a slightly reddish hue It does not pit upon pressure like ordinary dropsical effusion, but if firmly pressed with the tip of the finger it quickly rises to its former level As a rule, it gives rise to no annoyance, though some patients complain of a local sense of burning or scalding when it begins to appear

It is probably true that the alarming dyspnea and associated gastro-intestinal trouble are the result of the same edematous process going on within the mucous membrane Krieger's case, a typical one, was found dead in bed one morning and an autopsy showed that death was caused by sudden edema of the glottis Collins finds that out of seventy-two cases three showed their initial symptoms to be located in the stomach and in 34 per cent of them all, gastro-intestinal manifestations were of sufficient importance to attract notice The throat was involved in about 21 per cent of all cases, a fact which should be carefully remarked as death has more than once resulted from edema of the larynx The stomach symptoms are generally a sense of uneasiness and extreme tension, loss of appetite, enlargement of the epigastrium, colic, and sometimes profuse vomiting and intolerable thirst Osler says the pains may become so severe at times as to require the administration of morphia In my case there was at no time any marked pain, but an intolerable sense of fullness and of retained undigested matter, and a bloated appearance of the epigastrium The patient was generally constipated A colliquative diarrhea sometimes follows the disappearance of an attack The urine is often voided in large amount, but frequent examination of it reveals nothing out of the ordinary Complete exhaustion and nervous anxiety often terminate an attack It was with great difficulty that my patient could be persuaded that her heart action was normal, so weak and prostrated did she feel when recovering Between the attacks the general health is good

Angio-neurotic edema is probably related to hysteria but the suddenness with which it comes and goes, the absence of the usual, well-known stigmata of the latter and other symptoms, all tend to prove that it is not hysteria itself It is a functional trouble of the sympathetic and central nervous systems, but the cause and character of this trouble are, up to the present time, entirely unknown Plausible theories and shrewd guesses have been made but nothing of a positive nature has yet been actually discovered The disease is rarely fatal and autopsies have been exceedingly rare It is most decidedly a chronic affection, lasting now and then a whole lifetime It is happily only fatal in those rare cases where the edematous process attacks the mucous membrane of the larynx

---

[1] Meditzinskie Obozrenie, 1889 Sajous Annual

No remedy has yet been suggested for its relief Neither the disease itself nor the attacks are amenable to any known treatment The salicylates, especially the salicylate of soda, have given the best results in the hands of others as well as in my own By them the intervals between the attacks appeared to be lengthened, but as for lessening the severity of the attacks or in any way actually producing anything like a permanent cure I could not see that this or any other of the long list of remedies which I experimented with, was of the least avail Angio-neurotic edema is a unique affection which needs a great deal more study for its complete elucidation

INTRALIGAMENTOUS FIBROMYOMA COMPLICATING PREGNANCY AT FULL TERM, HYSTEROMYOMECTOMY, RECOVERY

BY RICHARD DOUGLAS, M D

NASHVILLE TENN

As the records do not abound with cases of complete hysterectomy for fibroid complicating pregnancy, I presume a detailed report of the following case will bear some interest

Mrs N, 33 years of age, a multipara, her youngest child was born five years ago All labors normal with uncomplicated convalescence During the year 1894 there had been some menstrual disorder, irregularity and at times profuse flow In May, 1895, she consulted Dr J W McCall for her uterine trouble, the result of the examination I report in his words "I made a digital and specular examination, was unable to find the os uteri The right vaginal vault and iliac region were filled with a hard tumor " The case passed from under Dr McCall s observation and was not seen by him again until March 8, 1896, when he was called in consultation with Dr Howard The patient had then been in labor sixty hours, supposed to be at full term Her physicians recognized that the pelvis was encroached upon by a hard tumor This tumor seemed to lie entirely in front of the os uteri, completely blocking the natural channel Recognizing the impossibility of delivering the child *per vias naturales*, I was telegraphed for, and with my assistant, Dr Barr, and nurse reached the patient about two o'clock on the morning of March 9, seventy-two hours after the onset of labor

That my readers may have some appreciation of the difficulties encountered in a country practice, I will say that my patient lived in a little box cabin about 12 x 20 feet, divided by a rude partition into two small rooms provided with none of the comforts and scarcely the necessities of life Amid these surroundings her noble self-sacrificing physicians had been in constant attendance, doing all in their power for the relief of the suffering woman, with no thought of pecuniary reward and with little hope of being able to save the patient.

Labor had been most violent and exhausting, but for the last twelve hours uterine contractions had almost ceased

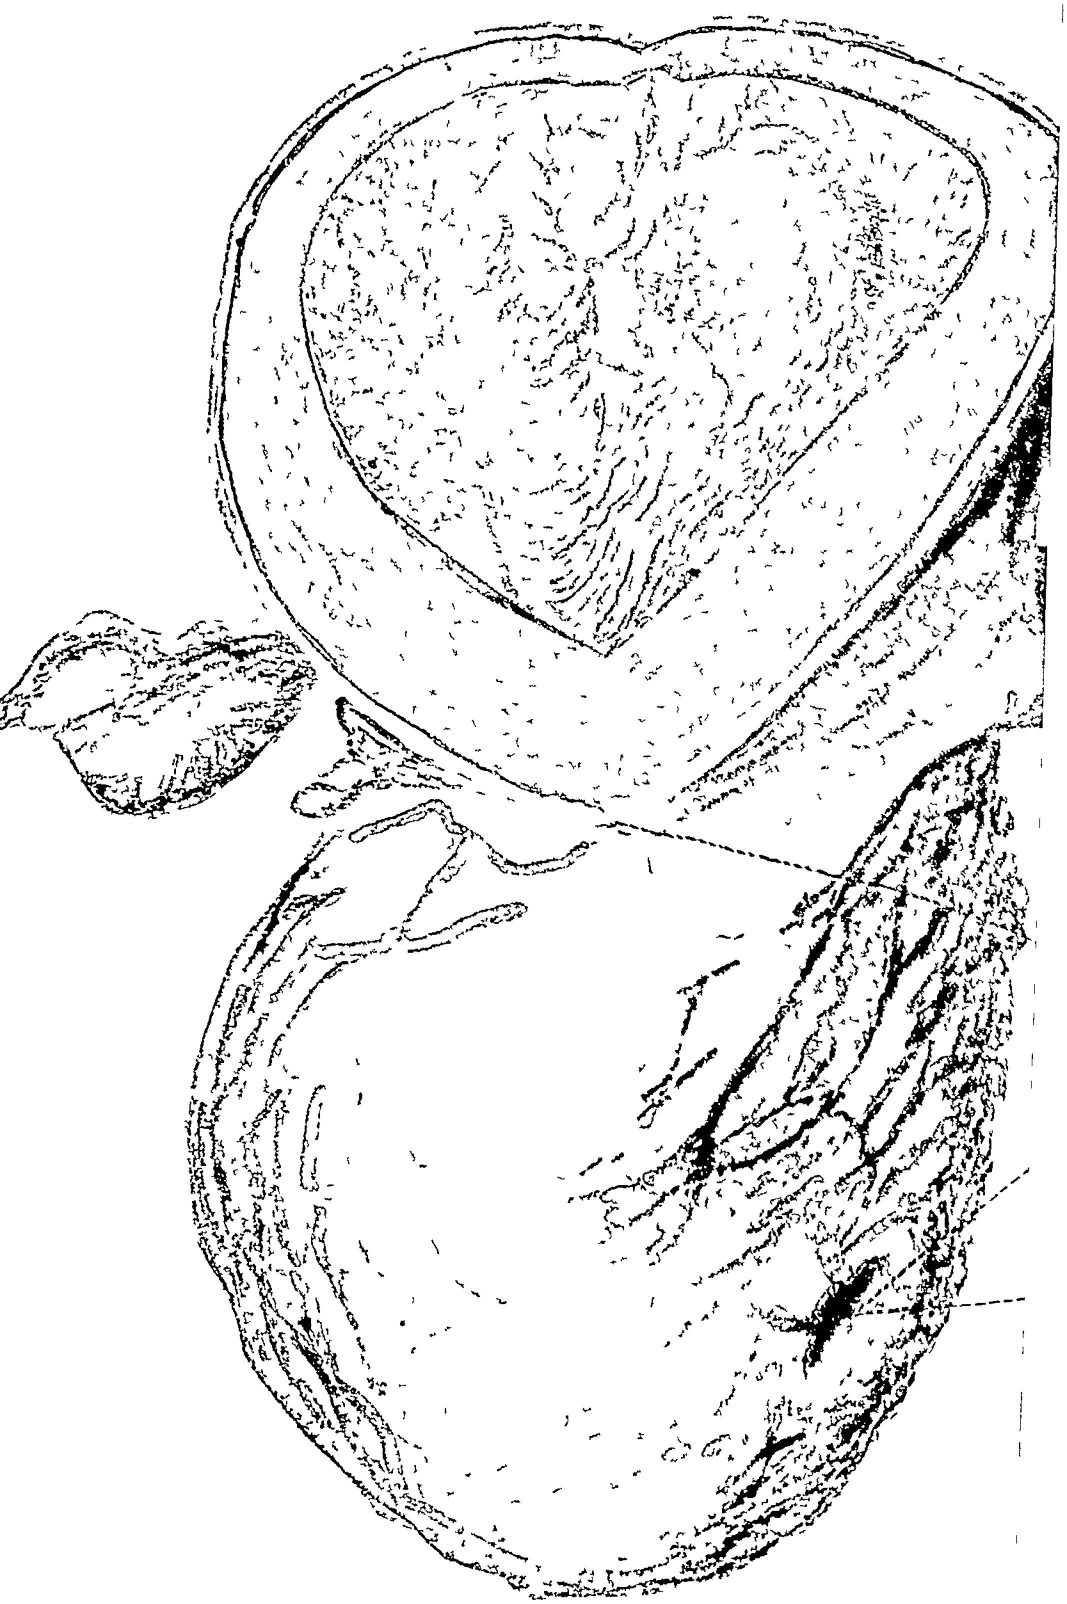
Notwithstanding the protracted labor the patient appeared in very good general condition Her pulse was regular and about 120, temperature 101 degrees patient remarkably quiet and composed Physical examination of the abdomen revealed rather an unusual morphology The abdomen was asymmetrically distended, unusually broad in its transverse diameter, widely bulging in the flanks, somewhat flat or depressed in the middle line The greatest enlargement appeared on the left side and above the umbilicus On palpation a round and very hard swelling about the size of an adult head could be detected in the right side The center portion of the abdomen was soft, elastic and compressible In the left side we could easily determine by manipulation a vertex presentation, the head resting in the left iliac fossa, occiput to the left, dorsum of child to mother's left side, a first position if in axis of pelvis There was no uterine contraction in response to our manipulation Fetal heart sounds could not be detected upon auscultation, the patient had not felt fetal movements for twelve hours

Vaginal examination revealed a capacious vagina, the entire pelvis was filled by a smooth, hard, inelastic tumor which was firmly fixed in the pelvis Every effort to raise it upward was ineffectual The os uteri was reached with the greatest difficulty, it lay very high up out of the true pelvis and to the extreme left side, could not reach the os sufficiently well to pass the finger beyond the margin of the right border of the cervix

Diagnosis—*Uterine fibromyoma springing from* the supravaginal cervix and the right side of the body of the womb firmly wedged in the pelvis, filling that cavity, displacing the uterus and occupying the hypogastric right inguinal and lumbar regions of the abdomen, pregnancy at full term, amniotic fluid escaped and the child in all probability dead Complete uterine inertia from exhaustion and inefficient contraction due to presence of the growth

After consultation with my associates it was determined that an operation was immediately demanded and that that operation should be in all probability a complete hysterectomy We discussed the propriety of Cæsarean section, but the idea of leaving so large a tumor with the dangers incident to the operation and puerperal state, were against such an incomplete procedure Furthermore, knowing the uterus to be in a state of inertia, hemorrhage after Cæsarean section appeared to our minds a danger of great moment Therefore determining upon hysterectomy as the only means of saving our patient's life, and gaining her consent to anything that we might deem best, we prepared with such poor accommodations as the place afforded for the undertaking

Preparation—An ordinary kitchen bench with the filth of ages upon it, covered however by a clean sheet, was the improvised operating table The bed served as a table for my instrument trays, one bowl and pitcher for sponge basins, and two dimly burning lamps gave us all the light we had Fortunately, my instruments, ligatures, sponges and towels had all been thoroughly sterilized and we managed to protect them from contamination Boiled water in abundance was supplied Notwithstanding the urgency of the case, much time was spent in careful aseptic pre-



Fibro-myoma complicating Pregnancy at Full Term Dr Richard

A, Cervical canal, 4 inches long B, Os uteri Reduced one third

paration of the patient, and after asepticizing ourselves as thoroughly as conditions would admit, the patient was anesthetized with ether by Dr J H McCall

Operation—The abdomen was opened by free incision from well above the umbilicus to the pubes The distended uterus was raised up and as well as its tumor would permit, out of the abdomen A hot towel was placed over the intestines and four provisional sutures were placed in the upper portion of the wound, crossed and given a half turn so as to draw the wound together and still further protect the intestines The uterus was observed to be somewhat rotated upon its axis, that is the right border presented to the center A large rubber dam was now placed around the uterus and made to hug it very closely and fixed with a safety pin to protect the cavity from blood or escaping fluid From the location of the tumor it was impossible for us to encircle the uterus with a tourniquet Therefore my first assistant, Dr Barr, grasped the cervix as low down as he could with both hands making firm pressure so as to control hemorrhage The uterus was opened as in Cesarean section, the child was seized by its breech and removed It was observed to gasp once Waiting a few moments the cord was severed between catch forceps and the child intrusted to a physician who made unsuccessful efforts to resuscitate it The uterus remained perfectly flabby, no contraction whatsoever and yet the hemorrhage was not very profuse, a few hot sponges placed in the line of the wound controlled it As we comtemplated removing the uterus the placenta was not disturbed The assistant still holding the uterus to control bleeding, I now proceeded with the hysterectomy The tumor was found to be an intraligamentous fibroid and it lifted the peritoneum entirely from the floor of the pelvis Ligating the right infundibulo-pelvic ligament, catching the tube and ovary with pressure forceps, I cut between With separate ligature the right round ligament was secured The Fallopian tube and round ligament were at least four inches apart, that is, the broad ligament was expanded to this extent by the tumor I next split open the broad ligament on the top of the tumor by an incision parallel to the tube and without difficulty peeled down the peritoneum before and behind and enucleated the tumor, which involved the right side of the body of the cervix of the uterus Lifting the tumor up I felt distinctly pulsating the uterine artery just as it ascended to the cervix Isolating it fairly well its deligation was securely effected Up to this point in the operation I had not come in contact with the bladder With the tumor now enucleated, attached only to the uterus and all vessels upon that side secured, I proceeded in the usual way with the left side Here I encountered the greatest difficulty After ligating the ovarian vessels the tissues were so hypertrophied, the veins so enormously distended and everything distorted, I was not quite sure of my anatomy, but dissecting the bladder from the anterior surface of the uterus and carefully avoiding the ureter I finally succeeded in ligating *en masse* a lump of parametric tissue in which was concealed the uterine artery I now separated the uterus from its vaginal attachments and quickly removed the entire organ with its attached tumor and contained placenta The bleeding was very profuse from numerous points, particularly from the anterior vaginal artery, and all of these were grasped with forceps and then securely ligated All these ligatures and those upon the uterine artery were left long and pushed into the vagina, the others were cut short The open broad ligaments were closed with silk sutures, the pelvis thoroughly cleansed and packed with gauze, the free end of which was carried into the vagina The abdominal wound was closed in the usual way The shock from the operation was comparatively slight considering the time one hour and fifteen minutes and the many difficulties we had to contend with The patient had reacted thoroughly in two hours after the operation and expressed herself as comfortable and determined to get well There is little to relate of the after-treatment of the case Thanks to the assiduous attention of her physicians, Drs Howard, McCall and Cox, and her excellent constitution, she made a quick recovery and is now a perfectly well woman

CATARRHAL DISEASES OF THE NOSE AND THROAT

BY J D ALBRIGHT, M D

AKRON, PA

To any careful observer, and all physicians should be such, it must have become apparent that catarrhal diseases of the nose and throat are becoming more and more frequent and play a most important part in the practice of every physician who gives more than passing attention to their treatment

There seems to be a prevailing opinion in the minds of many of our profession that the correct treatment of these diseases involve the use of special and expensive instruments and require a more than ordinary degree of skill to use them properly, so that these cases are allowed to drift to the specialist, who, by the way, is often no more than a physician who keeps posted and has the courage to apply his knowledge

By a moderate amount of study and diligent practice, by perseverance in the use of the methods at hand the general practitioner may overcome imaginary difficulties that seem to stand between him and success and he will be richly rewarded for his time and labor so spent The instruments that may be called necessary are A good light, a head mirror, a nasal speculum, a tongue depressor and a laryngeal mirror With these as aids in diagnosis, if the examination is conducted carefully, we are certainly in a position to diagnosticate the existing conditions and therefore treat them intelligently Among the laity there is much termed "catarrh" that bears no relation whatever to it, and in this disease more than in any other these people glory in making their own diagnosis, so that the physician is often taken off his guard and is led to treat catarrh on the strength of his patient's words instead of a careful examination We have different forms of this trouble 1, simple chronic rhinitis 2, hypertrophic rhinitis, and 3, atrophic rhinitis

Simple chronic rhinitis —This is a simple inflammation of the mucous membrane of the nasal cavity, without any structural changes Its only symptom is a discharge of mucus or sometimes, when of long standing, muco-pus On examination you will find a congested membrane, with here and there yellowish or whitish spots of mucus In the vault of the pharynx where there is much glandular tissue there will be a swelling, giving them a turgid appearance, and the secretion which covers them **will be** found to be more tenacious When these ca[illegible] a [illegible] he can with a certainty pred[illegible] only in the first stage, simple rhinitis, although of perhaps quite a long standing, getting no worse nor yet any better The treatment for this condition is as follows Cleanse the mucous membrane thoroughly with warm water, applied by means of a douche, such as the Bermingham, after which by means of the same douche or an atomizer, make an application of the following Glyco-thymolin (Kress) one part, water distilled, three to six parts This mixture should be used twice daily It will be found best to use six parts of water for a beginning and gradually strengthen until only three parts are used As before stated, there will very seldom be more than this treatment required in this form of nasal catarrh, as they at once proceed to recovery

Hypertrophic rhinitis —A certain number of cases suffering with simple rhinitis will neglect taking treatment until they have developed our second class, chronic hypertrophic rhinitis, and will then consult the physician Here, on examination, a different aspect presents itself, as we have first, marked structural changes, a proliferation of all the normal mucous membrane, making it of increased size, therefore called hypertrophic, enlarged The glands in the vault of the pharynx are also enlarged, subject to the same influence as the membrane of the nose The secretions are now thick and tenacious, which with the enlarged membrane occludes the air passages, causing difficult breathing, causing the voice to be nasal in character and causing the patient to become concerned about himself, perhaps for the first time In the treatment of this condition, all that I have said on the previous stage applies to this one, with more added Do not forget to cleanse the passages, this is the fundamental principle of successful treatment, and as such a saline solution, such as glyco thymolin (Kress), is practically the best remedy for the purpose It cleanses and it heals, it causes a proper degree of healthy stimulation, it acts as an antiseptic and is a most efficient deodorizer As the comfort of the patient is a desideratum, the use of a 5 per cent solution of cocain applied to the turgescent membrane is often advisable, covering the membrane which covers the inferior turbinated bones, in order to allow more freedom in breathing This may be done once or twice daily by the patient, at different times as occasion demands The action of cocain on these tissues is well known The cleansing solution and the cocain applications the patient can well himself apply, but the following application should be made in the office of the physician, as it can be more thoroughly accomplished, and I am of the opinion that the mind influence over the patient is better when he must daily visit the physician, it reminds him that he is under treatment and thus prevents his neglecting the home treatment For the following remedy a good atomizer should be used, with a nasal tube, and a long tube for the pharynx, and an application should be made once daily, while necessary This will cure Iodin 3 grs, potass iodid 10 grs, zinc sulpho-carb 15 grs, glyco-thymolin (Kress) 1 oz, aqua q s, ad 4 ozs Mix Sig Use as above stated This treatment kept up for a month, or perhaps longer if a serious case, will do its work well

Atrophic rhinitis —This form is caused at times by neglecting the disease when in the hypertrophic stage, and is essentially a death of the tissues The tissues were crowded to death by the enlargement Here there is plenty of room in the nasal cavity, there is no interference with the voice or breathing, the secretions are hard and in the form of crusts, the posterior wall of the pharynx will be seen to be dry and shiny, the sense of smell is interfered with, sometimes destroyed, there is at times pain in the frontal sinuses, or in other parts of the head, the patient is irritable and very sensitive to atmospheric changes

These cases are very often afflicted with a fearful odor, very often on this account do they consult you Our words of encouragement to the patients suffering with the two varieties preceding must now cease, for unfortunately the cure of atrophic rhinitis is in most cases beyond us, be careful then what you promise your patient Promise nothing but relief, and if occasionally one case or another leaves you satisfied that you have cured him, restored his sense of smell or hearing do not become elated, for if you thus set up your standard you will very often meet with bitter disappointment

The indications we wish to meet in these cases to afford our patients relief are two-fold, cleansing and disinfecting and I may add keeping them thus and attempting to regenerate the atrophied membrane, which as before said can be but very seldom hoped for The first indication of cleansing and disinfecting is met by daily washings with the solution before given of water and glyco-thymolin, three of the former to one of the latter, so as to remove all offending secretions Occasionally these crusts must be removed by means of a forceps, which if necessary must not be neglected A spray of liquid vaselin to which a little camphor has been added, after these washings, will be agreeable to the patient, as it will prevent the annoying dryness of the air passages, and I doubt not but that it is of some remedial value

For the purpose of stimulating and regenerating the atrophied mucous membrane there are recommended, salicylic acid galangal root, nitrate of silver, etc, blown into the nose by an insufflator, but I can not but repeat myself and say that this will very seldom be accomplished, and he who is careful will never promise nor yet expect it Regarding the internal treatment of catarrh, I have never seen any good result from its use and I think the consensus of opinion of the entire profession, the regular, hold that it is a local disease and as such requires only local treatment Constitutional defects must be recognized and treated, but the remedies employed have no effect on the catarrh, *per se*

THE STATISTIC EVIDENCES OF THE VALUE OF VACCINATION TO THE HUMAN RACE, PAST, PRESENT AND FUTURE

Read before the American Medical Association at the Jenner Centennial Celebration held at Atlanta, Ga, May 1896

BY EUGENE FOSTER, M D

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE AND STATE MEDICINE AND DEAN OF THE FACULTY OF THE MEDICAL DEPARTMENT UNIVERSITY OF GEORGIA AUGUSTA GA

(*Continued from page 862*)

PROPOSITION 10

If the operation of vaccination be done with due regard to the rules of modern aseptic surgery, with due regard to the health of the individual vaccinated, and proper precautions be observed in obtaining and using vaccine lymph, there need be no apprehension that vaccination will injure health or communicate any disease other than vaccinia

Antivaccinists seriously contend that "Vaccination propagates syphilis, consumption and hereditary diseases, which appear years afterward at their appointed time It produces immediately erysipelas, and aggravates the disorders of childhood, destroying the germs of the teeth during teething It is especially productive of mesenteric and glandular diseases, and lies at the foundation of the shameful mortality of whooping cough "

Mr P A Siljestrom (who the *Vaccination Enquirer*, the journal of the antivaccinists, says is "one who has mastered the vaccination question") states, "It has been proved that disease (especially erysipelas and syphilis) and death have not infrequently been observed to result from vaccination "

Mr P A Taylor, M P , of England (another leader of the antivaccinists) says, " Not tens but hundreds of thousands of persons in this country (England) have mourned the death or ruined health of their children through the results of vaccination "

The above are fair samples of objections raised against vaccination by antivaccinists, and if it can be shown that either or all of the above assertions be true, then the medical profession of the civilized world has for the past century been most grossly careless and ignorant in accepting and recommending vaccination as a prophylactic against smallpox

Let us, then, once again carefully examine these objections, and decide if or not they be well founded

As preliminary to a full consideration of these points I submit, and endorse, the following from John Simon of England, one of the ablest, most renowned and conscientious sanitarians and medical philosophers of this century—a man who has more exhaustively, ably and impartially investigated the vaccination question than any other physician living or dead Simon says

" Is properly performed vaccination, then, an absolutely inoffensive proceeding? Not at all, nor does it pretend to be so The very meaning of the thing is, that it shall artificially and designedly produce a transient and trifling indisposition , that for some days the infant shall be uncomfortable with a sore arm and a slight irritation of the adjacent axillary glands, and a perceptible amount of general feverishness Within the limits of this description, one child may be a little more, another a little less, inconvenienced , but those limits are rarely exceeded And if it can not strictly be said that the immediate effects of well performed vaccination never exceed the intentions of the vaccinator, at least it may be affirmed that any permanent injury resulting from it is an accident barely known in the practice of surgery

" Persons hostile to vaccination allege against it, that it produces eruptions on the skin and glandular swellings, and others, not unfavorable to the practice, doubt whether this to some extent may not (and especially as regards unhealthy predisposed scrofulous children) be a true allegation

" Vaccination might afford to bear these imputations For, to what do they amount? Were they ever so true, the alleged evil, even to the sufferer, would be little in comparison with his gain , and the total amount of such evils, compared to the social advantages of vaccination, would, literally speaking, be too small to appreciate

" But in fact, the imputation is—at least generally—erroneous There is in it again that common fallacy of calling whatever happens after an event its effect Propter, quia post The infant is commonly vaccinated at three or four months of age Thus whatever physical or moral evils belong to human life are very likely to have been preceded by vaccination , and it is not extraordinary that, especially by ignorant persons, this operation should often be charged with producing incredible results When you consider, too, that the few months after vaccination include events which are very critical to infant life, you will see what frequent room there must be for misconception Even to the healthiest and best cared for of children, weaning and teething are not perfectly safe and comfortable processes , to delicate and ill nurtured children they are often fatal , to vast numbers they occasion, sometimes during many months distressing or alarming symptoms Such symptoms I need hardly tell you, affect both vaccinated and unvaccinated They have been known as incidental to infancy from periods long anterior to Jenner's existence Now, an extremely frequent one of such symptoms is an inflammation of skin (known by the technical name of eczema infantile) producing on the child's face and head, or on other, perhaps many or most parts of the body a dense eruption of little pimples, which presently convert into an itching and discharging surface so much of the skin as they occupy , and since irritations of the skin are peculiarly apt to propagate themselves in the direction of the return current of the circulation of the blood to certian organs, the so called lymphatic or absorbent glands which are subsidiary to this circulation, so it very commonly happens that more or less irritation and swelling of these glands will accompany that eczematous eruption , and that, for instance, the child who has the eruption about its head and face (which are among the most usual seats of the unsightly disease) will often be still further disfigured by glandular swellings in the neck Though I have spoken of this infantile complaint as incident to the time of teething and weaning, yet in fact it may arise at earlier periods of life, even within a few weeks of birth, and, of course, before vaccination as well as after it Indeed, frequently it is a reason for which vaccination is postponed , and perhaps I give you no readier means of estimating how little vaccination has to do with its occurrence, than by telling you, first, that before the discovery of vaccination smallpox inoculation was charged with producing it and, secondly, that in 1714, when smallpox inoculation was yet unknown in England, Dr Daniel Turner expressed himself in the following terms 'Among diseases of infants and young children scarce any attends more frequently that pustulary or scabby eruptions in several parts of their bodies, as in the breech, but more especially their foreheads, brows and other parts of the face, which we find oftentimes overrun with dry and crusty scabs '

"The circumstances under which both infantile eczema and glandular swellings arise are familiarly known to the medical profession To say that properly performed vaccination can have directly to do with them, that it can directly cause general eczema, or directly affect any glands but those which it is intended and expected to affect would be an assertion not warranted either by practical experience or by any pathologic probability To say that indirectly it may do so, that in the very few instances where it produces excessive results, the disturbance that, under such very exceptional circumstances, it may for the time of its operation predispose the child to this complaint and to that, may excite the scrofulous child to show its scrofula, and the eczematous child to show eczema, these are assertions which may or may not be true , which are more easily made than either established or refuted , but which, if admitted in their utmost scope, really allege against a cold in the head, a cut finger, an undigested meal, or any other one of the thousand minor accidents of everyday life

' So much for what has been alleged against properly performed vaccination, against such vaccination as alone ought to prevail in any country where the State requires its performance So much for the drawbacks which have falsely been said to detract from its inestimable advantages, and the dangers which, with almost equal fasehood, have been said to attend its performance

" It is less easy and less necessary to dispose of what may be said against ill performed vaccination , understanding in this phrase not merely such vaccination as is done with an unskilful hand, for commonly the worst effects of clumsiness is only that the operation fails , but especially referring to such vaccinnation as is done without due inquiry into the health of the child to be vaccinated, or without due care for the quality of the lymph to be employed

" If local scandals have arisen against vaccination, and if some prejudices against it seem to have in them a show of reason, those are the sources from which such serious evils have come All that belongs to the mere manual trick of vaccination is learnt from a minute's teaching and an hour's practice , but not so easily the philosophy of the procedure, or the precautions which are requisite to make it harmless and useful From Jenner onward, all great masters of vaccination have urged that its merits will always appear proportionate to the merits of the performers , that if sickly children are vaccinated without due regard to their actual condition of health, children teething, and the like , or if children, healthy or unhealthy, are vaccinated with improper material, the results must be at least unsatisfactory, and possibly dangerous And all competent persons accordingly recognize that one who would vaccinate must thoroughly study these things

' Especially as regards the quality of vaccine lymph, the careless or uneducated vaccinator is using a dangerous weapon It is only during part of the course of a vaccine vesicle that its lymph is suitable for further vaccinations , for after a given moment, at which the contents of the vesicle possess their maximum of simple contagiousness they tend more and more toward the quality of common inflammatory products and matter now taken from the vesicle is no longer the simple agent of a specific infection, but both has less efficiency for its real purpose, and is specially able to produce other undesired results A danger of somewhat similar kind is that of taking lymph from vesicles which already have been accidentally ruptured, or where from any other cause, local or constitutional, their specific fluid is likely to have been modified by common irritative processes Still more critical changes occur in lymph when removed from the body, unless appropriate means be taken to preserve it , for u [illegible] ce of [illegible] and moisture it tends, like other d [illegible] out decomposition and inoculation w [illegible] can hardly be more useful or less dangerous than a casual scratch inflicted in the dissecting room According to the usual practice of vaccination, error is less likely to be committed in this particular than in the one first mentioned, for, when the operation is not performed from arm to arm, use is very generally made of lancets or ivory points on which lymph has been allowed to dry Under this system (at least in our climate) the matter is almost secure from change, and there is little room for such accidents as might arise from failure in those delicate procedures by which lymph is sometimes kept moist for use But the danger of taking matter from irritated vesicles, and and from vesicles at too advanced a period in their course, is one which circumstances render frequent, and there is reason to believe that in at least a very large proportion of those cases where abnormal effects have resulted from so called vaccination, it has been the employment of this ambiguous irritative matter which has occasioned the mischief and scandal

"Suspicions are sometimes expressed that a slovenly vaccinator, careless in his choice of lymph, may thus cammunicate to one child the constitutional or local disease of another If this be true it were nothing against vaccination It is no argument against bread that alum constipates the bowels, still less is it an argument against quinin that some drunken shop boy may give one strychnin instead of it And, without intending disrespect to gentlemen whose opinions on this point may be less decided than my own, I must say that I believe it to be utterly impossible, except under circumstances of gross and punishable misconduct, for any other infection than that of cowpox to be communicated in what pretends to be the performance of vaccination A vaccinator must forget his duty in more than one particular, he must be indifferent both to the feelings of others and to the social progress of the great good which he claims to administer, if he affronts the natural antipathies of those who bring their children to be vaccinated by drawing the lymph for vaccination from the vesicles of diseased subjects And, practically speaking, I can conceive of no circumstances in this country which justify a departure from the rule (recognized by the medical profession as unreservedly as it is desired by the public) that lymph be taken only from healthy subjects

"But, supposing that, in breach of this rule, lymph be taken from Jennerian vesicles on the arm of a subject suffering constitutional disease, what then? On the assumption only that it be a true Jennerian vesicle at the proper period of its development, there are cogent reasons for believing that such vaccination can produce none but normal results

"There is one simple mass of experience, which, to my mind, seems conclusive It has been proved on a large scale that vaccin lymph, taken from persons actually suffering from smallpox, conveys to those who are vaccinated with it no other than the vaccin infection This most remarkable truth has been established, I say, on a large scale, for, not once or twice, but at least hundreds of times, something to the following effect has occurred A patient has been vaccinated a little too late for protection Warned of his danger he has had recourse to vaccination when already smallpox was in his system, and (under a law which expresses the intimate affinity of these two agents) the operation of the inhaled variolous contagion, and the opperation of the inoculated vaccin contagion, have proceeded simultaneously on his person, the former producing the general eruption of smallpox, the latter producing at the vaccination spots characteristic Jennerian vesicles And with the lymph of these vesicles, again and again, successful vaccination has been performed Again and again it has been shown that such lymph is capable only of communicating the Jennerian infection

"Since then it is a quite unquestionable certainty that, even the system is drenched with that subtlest infection of smallpox the Jennerian vesicle preserves its own contagion pure and isolated, the argument may reasonably be extended And, even if there were no evidence in relation to other diseases, this analogy would have rendered it eminently improbable that any, the most infectious, of their number could admix its contagion with the specific products of cowpox Indeed, so definitely and so constantly characterized are those local changes which different morbid poisons severally and specifically produce, that to say of a given phenomenon 'this is a typical Jennerian vesicle' is, I believe, tantamount to saying this is a vesicle, which only one modified influence can produce, which no second influence can concur in producing, and in the contagion of which no second principle of infection can possibly reside

"Turning, however, from these general considerations, I may inform you that the diseases which it has been suspected that vaccination might communicate have chiefly been scrofulous and syphilitic complaints, and various eruptions of the skin In all but a very limited number of these cases it may be conclusively answered that the suspected mischief is physically impossible Scrofula, for instance, and most skin diseases, even when for experiment their specific discharges and other products are deliberately inoculated on the healthy, are absolutely incommunicable by contagion, and it is inconceivable that the vaccin lymph, even if it could include these products, would alter the essential condition of their nature Of some others among the diseases referred to, it may no doubt be admitted that certain of their products are infectious, but then again comes the question (which is already by anticipation almost disposed of) whether the constitutional existence of such diseases can qualify the contents without modifying the characteristic development of a true Jennerian vesicle

"Experiment, where it has been deliberately addressed to the solution of this question, has invariably answered, no, and such experiment is worth many arguments "

After quoting from M Taupin, Simon says

"I am not aware of any counter experiments suggesting different conclusions to those which are expressed and justified in the preceding passage They assert for vaccin lymph the principle which Dr Mead a century ago asserted for the virus of smallpox inoculation It is more material into what kind of body it be infused than out of what it be taken Indeed, in the whole list of diseases syphilis is the only one to which serious suspicion will attach, and, in regard to its communicability by the lymph of a true Jennerian vesicle, various other observers confirm the accuracy of M Taupin's result

"Moreover, Professor Sigmund of Vienna (whose researches on everything relating to the inoculation of syphilis have been on a very large scale) has added to M Taupin's results, one which quite in a different manner, is equally against the possible invaccination of syphilis In an official report on the division of the hospital over which he presides (Aertzlicher Bericht des Allgem Krankenhauses, Wien, 1855) he relates experiments to show that syphilis in its inoculable form prevents, within the sphere of its infection the simultaneous formation of a vaccin vesicle The discharge of chancre (in which form alone syphilis is universally recognized to be inocuable) has been designedly mixed, as by nature it never could be mixed, with ordinary vaccin lymph, and insertion of this compound poison in the skin has been followed only by the ordinary local results of syphilitic infection No Jennerian vesicle had been formed No signs have existed of any possible combination of the two infections Dr Friedinger, who conducted these important experiments in Professor Sigmund's wards and under his observation, has also communicated their result to the society of surgeons at Vienna

"It is unquestionable, however, that cases are recorded in which the lookers on (sometimes including a medical practitioner) have believed syphilis to have been communicated by vaccination A moment's reflection suggests that in such cases there must generally be sources of fallacy, which render them, in contrast with experimental results, almost valueless for instruction When a child is born with a heritage of syphilis (a very frequent incident, if the parents have been suffering from that disease) the characteristic symptoms commonly do not appear till some weeks after birth And then the scandal discloses itself Now, among persons with any sense of shame, the knowledge that one had transmitted syphilis to one's child would always be a sore subject There would be strong temptations to employ false pretense Not only would parents often conjointly wish to disguise from their medical attendant or from members of their household, the real explanation of the child's ailment, but also, not unfrequently, one parent would wish to conceal from the other that the origin of the disease had been a conjugal infidelity In respect even of unmarried people, every surgeon knows what utterly false, far fetched and absurd explanations are given of syphilitic symptoms primary and secondary, and it requires little experience to imagine how much more pertinacious will be the demand for excuses, and how much more active the supply of falsehood, under the complicated circumstances of connubial syphilis Accordingly it is a matter of surprise that vaccination has not almost generally been pitched upon by persons in search of an apology for their syphilitic children But in truth even such allegations against it have been few and their paucity (assuming them all to have been made in good faith) would be a strong reason for regarding them with mistrust, for surely if syphilis could be diffused by the vaccin lymph of children with an hereditary taint of that disease, this possibility must long ago have been made evident on a scale far too considerable for question

"Among the scanty number of recorded cases in which such allegations have been made, there are, however, some in which, so far as I can judge, it seems almost certain that a person pretending to vaccinate did really effect a syphilitic inoculation Properly to estimate these grevious instances of mal practice, two considerations must be adverted to 1 To the already quoted negative results obtained by Taupin and many other observers in their experimental inoculations of lymph from the true Jennerian vesicle of syphilitic children 2 To the fact that secondary syphilis itself is very possibly not communicable even by direct inoculation of matter from the ulcer and eruptions which it occasions, for many of the ablest experimenters in Europe declare that in hundreds of trials they have never once succeeded in thus conveying from person to person the slightest infection of syphilis And, regard being had to these considerations, it becomes almost certain that in the cases referred to the matter of chancres, the matter of primary syphilis was used instead of vaccin lymph by the vaccinator, a mistake (however it may have occurred) of so gross and criminal a nature that the medical profession would feel no sympathy for the person through whose neglect or incompetence it happened

"But in coming to cases of this description there is no longer question of the merit of vaccination If recorded instances of the kind, instead of being so few that you count them on your fingers, were of innumerable frequency, they would make no argument against vaccination Only they would if possible, render more obvious than it is the expediency and duty of providing that this great self defense of nations against pestilence be not ignorantly and recklessly administered

"Here, indeed, is the whole gist of the matter Earlier parts of this letter have shown that by vaccination, properly administered, the once enormous fatality of smallpox may be reduced to nothing The present section justifies a conclusion that against this vast gain there is no loss account Of the various alleged drawbacks to such great advantages the present state of medical knowledge recognizes no single trace Jenner's discovery, properly utilized, has been a pure blessing to mankind, an unmixed addition to the strength and happiness of nations

"To say of vaccination that it has sometimes been ill administered, to say that under the pretext of its administration harm has sometimes been given instead of good, poison instead of antidote, is to speak, not against it, but, whether rightly or wrongly, against its administrators The vaccinations of Europe are now counted annually by millions It may be vain to hope that every lancet shall be used with equal skill and equal carefulness, or that all populations shall be equally anxious to render the operations successful, but Medicine at least has contributed her share in showing that, subject to these conditions, smallpox need cause no further fear nor its antidote be accepted with mistrust"

So much for the general principles controling the question of objections to vaccination presented by John Simon

(*To be continued*)

Report of the Surgeon-General of the Army for the Year Ending June 30, 1896

The following is an abstract of Surgeon General Sternberg's report, omitting financial statements, special reports of medical officers, statistic tables and other matters of detail

War Department, Surgeon General's Office,
Washington, D C Sept 8, 1896

Sir I have the honor to submit the following report of my administration of the duties of this office during the past year Beside the health of the troops and the sanitary condition of the various military posts, this report relates to certain duties imposed upon the Surgeon General of the Army by the Revised Statutes of the United States and by Acts of Congress making appropriations to be disbursed under his direction

Among the expenditures authorized by Congress for the year ended June 30, 1896, were those for artificial limbs and their commutation, for appliances for disabled soldiers, for trusses, for the support and treatment of destitute patients in the city of Washington, D C, for the Army and Navy General Hospital, Hot Springs, Ark, for the Army Medical Museum and Library of the Surgeon General's Office, for the construction and repair of hospitals, and for medical and hospital supplies for the use of the Army

Artificial limbs and their commutation —During the fiscal year ended June 30, 1896, 21 artificial legs were furnished and commutation was paid in 101 cases of amputated leg, in 69 of amputated arm, and 13 of amputated foot Commutation was paid also in 2,402 cases in which the use of a limb was lost

It is believed that the appropriation of $575,000 for the year ending June 30, 1897 will suffice to cover the benefits accruing to the pensioners during the current year

The amount required for the year ending June 30, 1898, will amount to about $183,000 This estimate is based on the fact that of the appropriation of $194,000 for the fiscal year 1895, $184,192 55 was disbursed during that year, and $7,610 74 during the year 1896, making a total of $191 803 29 disbursed from the appropriation As these benefits recur every three years, an appropriation will be required for the year ending June 30, 1898, approaching in amount to the sum expended from the appropriation for the year ended June 30, 1895 The actual amount that will be required will depend on the number of those paid in 1895 who are found to have survived the interval of three years As well as can be learned from the statistics, the death rate is about 1 6 per cent annually, or 4 8 per cent for the three years The estimate for the fiscal year would, therefore, be the amount paid in 1895 lessened by 4 8 per cent, or $183,000

Appliances —The number of appliances issued to disabled soldiers during the year was 162, for which was disbursed a total of $1,245 22

Trusses —There was expended in furnishing and fitting trusses to disabled soldiers under Sections 1,176 to 1,178, Revised Statutes of the United States, and the Act of March 3, 1879, the sum of $7,699 70 The number of trusses issued and fitted during the year was 1,106

Providence Hospital —The Act of Congress approved March 2, 1895, appropriated $19,000 for the support and medical treatment of destitute patients in the city of Washington, D C The amount of relief afforded under this appropriation was equivalent to the treatment of 114 patients throughout the year

Army and Navy General Hospital, Hot Springs, Ark —Twenty five officers and eighty five enlisted men were treated during the year The special advantages afforded by the Government in this General Hospital in the treatment of the diseases mentioned in Circular No 16, A G O, Dec 8, 1892, do not seem to be appreciated properly by medical officers of the Army It is equipped with all the latest and best appliances for the treatment of patients by hydrotherapy, electricity, massage and Swedish movements No sanitarium or private establishment at Hot Springs offers any such advantages It is believed that if cases suitable for treatment at the Springs were sent earlier in the progress of the disease many serious complications might be prevented and recovery effected in a larger percentage

Army Medical Museum —The total number of specimens received during the year was 890, number on hand June 30, 1896, 33,746

Library —The total number of books in the Library is now 120,344, of pamphlets and theses 199,600 Volume i new series, of the Index Catalogue includes the letter "A" and forms a volume of 828 pages It is now in the hands of the binder and will shortly be ready for distribution The manuscript of Volume ii, new series, is in the course of preparation for the printer, the usual appropriation having been made for this volume

Medical and hospital supplies —The approximate value of the medical supplies actually issued during the fiscal year ended June 30 1896, is $97 697 38

Advantage was taken of the preparation of the new Manual for the Medical Department of the Army to revise the Supply Table included therein Many new remedies were added and the allowance of others was increased where experience had shown this to be advisable Several recent medical works have been distributed for the use of medical officers Appliances for operating in accordance with the requirements of aseptic surgery have been issued to sixty five post hospitals The facilities for prompt and successful surgical relief are now much more satisfactory than they have been Portable bath tubs on wheels, adopted to giving a patient a bath at his bed side in cases of fever, have been issued to most of the posts

The hospital corps —There were in the service June 30 1895, 116 hospital stewards, 82 acting hospital stewards and 530 privates, making a total of 728 men The loss during the year by discharge transfer, retirement, death and desertion amounted to 270 men and the gain to only 249 men, a net loss of 21 men There were, therefore, in service at the close of the last fiscal year 707 men, of whom 106 were hospital stewards, 94 acting hospital stewards and 507 privates, the quota under existing regulations being 741

The appropriation bill provides that no appointment to the grade of hospital steward shall be made *until the number of* such non commissioned officers in service is reduced below 100 As there are now 106 in the corps it is not likely that an examination for appointment to this grade [illegible] ome time to come. Examinations for the position of acting hospital steward were held in November, 1895, and May, 1896. The successful candidates numbering 31 out of 43 recommended for examination have been detailed to duty in their new positions.

The issue of hospital corps knives and side arms has been discontinued. Members of the corps may, however, by Circular No. 2, Headquarters of the Army, A. G. O., Feb. 6, 1896, be furnished with firearms during Indian wars or when left with sick or wounded under circumstances which justify the expectation that their rights as non-combatants will not be recognized.

The new litter, model of 1895, is now being issued to military posts. A new edition of the Drill Regulations of the Hospital Corps was necessitated by the adoption of this hand litter. The litter slings of the hand litter previously in use were attached to the handles of the litter, and in the drill provision was made for the disposition of the sling in all movements. By detaching the sling and making it a part of the equipment of the bearer to be worn over the shoulders with the ends tucked under the belt in front when not in use the drill has been much simplified. When the litter is to be raised or lowered the bearers have merely to slip the loops at the free ends of their slings on or off the handles. Special instruction in the duties of litter bearers and in the method of rendering first aid to the sick and wounded is now given to all enlisted men of the army by their company officers in accordance with G. O. No. 9, Headquarters of the Army, March 13, 1896.

A change has recently been made in the method by which certain of the recruits for the Corps are to be instructed in their special duties. It consists in the disbandment of the company of instruction at Fort Riley, Kans., and the distribution of the men constituting the company in small detachments at selected posts. Hitherto the expense involved in transporting men to a distance has prevented the posts on the Pacific Coast and on the Northwestern frontier from being supplied with men educated in the company of instruction. By distributing the men and educating them hereafter in small detachments, each department will have its quota of men under instruction from which assignments may be made with less expense for transportation than if Fort Riley continued to be the center of distribution. Emergencies in the East will be met as heretofore, by drawing on the company of instruction at Washington Barracks, D. C.

Since the close of the fiscal year favorable action has been taken on my recommendation that the issue and use of a full dress uniform for the men of the Hospital Corps be discontinued. These men even on parades and occasions of ceremony have always to be in readiness to render service in case of accident and sudden sickness. Fatigue uniform is more suitable for such work than the full dress suit. The change will be of benefit to the men otherwise than by relieving them of an unnecessary uniform, for by drawing the value of the discontinued articles in white cotton duck clothing they will have a sufficient allowance for ward service, which has not hitherto been the case.

Army Medical School. The report of Colonel Charles H. Alden, President of the Faculty of the Army Medical School shows the course of study pursued and the excellent results attained during the session 1895-96. I heartily concur in his recommendation that the final rank of the student officers in the army should be made to depend on a combination of their marks at the examinations at entrance into the service and at the close of their school work. At present their relative rank is settled by the results of the examination at entrance and their work during the session does not alter it. A very desirable incentive to secure every advantage from the practical courses of the school would be obtained if the class standing of the students were made to influence their future rank.

Recruiting.—The total number of men examined for enlistment was 17,615, of whom 8,643 were accepted, or 480.83 of every thousand examined. The ratio of accepted men was higher among the colored men, 510.57, than among the whites, 486.46.

Of every thousand accepted recruits 727.18 were natives of the United States, 659.38 whites and 67.80 negro. In 1894 the ratio of native born recruits was 679.99, and in 1893 665.95. Of foreign nationalities Germany and Iceland furnished the largest proportionate numbers, 88.97 and 75.41 per thousand recruits.

The average height of these recruits was 67.51 inches, the native born white recruit 67.68 inches, being somewhat taller than the negro 67.37, and fully half an inch taller than the foreign born recruit, whose average was 67.14 inches. The foreign born recruit had the advantage over the native born white in weight, the former averaging 117.18 pounds, the latter 115.68. The negro exceeded both, his average being 140.85 pounds. In chest measurement and expansibility also the advantage appears to have been with the foreign born recruit, his measurement at expiration and inspiration being 34.80 and 37.73 inches, as compared with the native born white who averaged 34.26 and 37.17. The corresponding measurements of the negro were 34.27 and 36.89 inches.

Identification of deserters.—From July 19, 1890 to Aug. 31, 1896, the whole number of identifications made by means of outline figure cards was 759. Of this number 18 were made in the calendar year 1890, 111 in 1891, 215 in 1892, 104 in 1893, 110 in 1894, 121 in 1895, and 80 during the first eight months of 1896.

The 121 identifications made in 1895 represent the "repeating" element of 4,929 recruits whose outline cards were examined, *i. e.*, of every thousand recruits from civil life 24.55 were identified, through the outline cards, as deserters, military convicts or otherwise bad characters. Fraudulent concealment of former service is still practiced extensively, and but for the almost certain detection indicated by them it is reasonable to suppose that the practice would attain its former dimensions.

Uniformity in medico military statistics.—I have embodied in this report the data concerning the recruiting, sickness and mortality of our army during the calendar year 1895, tabulated in the form suggested by the International Commission of Military Medical Officers which met at Budapest in September, 1894. The Commission recommended that the various army medical departments begin publication with the statistics of the calendar year 1895 but as at this time last year I had at command all the data for 1894 needful to the construction of International tables for that year, I submitted the first set of these tables in my last annual report. Copies of the report were sent to the members of the Committee and to the Chiefs of the Army Medical Departments represented at the Budapest meeting. Reports in exchange are not expected from any of the foreign offices until the publication of their statistic data for 1895.

Medical Department of the National Guard.—The interest taken by medical officers of the Army in the progress and methods of the Medical Department of the National Guard, is well shown by an examination of the program of the sixth annual meeting of the Association of Military Surgeons of the United States, held at Philadelphia, May 12 and 14, 1896. Out of twenty-seven papers announced by the program as to be presented for the consideration of the Association, sixteen were by officers of the medical department of the Army, five by medical officers of the U. S. Navy, and six by officers of the National Guard.

HEALTH OF THE ARMY

It is with much gratification that I report the health of the Army during the year 1895 as having been excellent. All the rates that are usually considered by statisticians as throwing light on the physical condition of a community have been lower than in any previous year of the recorded history of our army. In 1894 we were fortunate in having all the rates except the death rate lower than ever before. In 1895 all the rates except the admission rate for injuries fell below those of the previous years and the death rate below that of 1889, which was the lowest on record. It is customary to compare the rates of an army with those of the other troops, or the rates of a military department, garrison, city or other civil or military community with those of other similar communities. Such comparisons are of value as indicating insanitary influences at work in one place and not in the other. They lead to inquiry into the causation of excessive rates and to the institution thereafter of remedial measures. But to determine the absolute condition of a community as to health it must be compared, not with other people under other conditions, but with itself under its most favorable conditions. Its proper standard of comparison is, therefore, its own best annual record. The nearer it approaches its best record the higher its standard of health under conditions which usually affect the individuals.

That progress is being made in eliminating insanitary conditions or other causes which tend to affect injuriously the health of our troops is shown by the fact that during the past year the sick rates have been lowered so much that they henceforth become the standard of comparison for future years.

The admission rate to sick report numbered 1,110.22 per 1,000 of strength, as compared with 1,089.73 in 1894, the lowest previous rate, and with 1,329.94, the average annual rate for the preceding decade. The average number of days each case was treated was 11.1, as compared with 11.6 and 11.7 respectively for the previous year and the average of the previous decade. The admission rate for disease was only 837.53, as compared with 845.52 in 1894, while the rate for injury was 272.69, as compared with 244.21.

The number constantly sick was 33.89 per 1,000 of strength as compared with 34 49 during 1894 and 41 87 as the average annual rate of the preceding ten years The number of days lost on account of sickness by each man of the army was 12 4, as compared with 12 6 in 1894 and 15 3 during the preceding ten years

The rate of discharge for disability per 1,000 of strength was 9 15, as compared with 13 30 in 1894 and 23 77 annually in the preceding ten years The discharge rate on account of disease was 6 81, on account of injury 2 34 The absolute number of discharges was 250, of which 186 were for disease and 64 for injury

The mortality rate from all causes was 5 16 per 1,000 of strength, as compared with 6 69 in 1894, 7 85 for the preceding decade, and 6 33 in 1889, the year of lowest record Deducting the rate for injury, 1 61, the death rate for disease was only 3 55 per 1,000, and compared with 3 95 in 1889 and with 4 76 in 1885, which until now held second place on our records The absolute number of deaths was 141, of which 44 were occasioned by injury

The mean strength of the command, officers and men, white and negro, from which medical reports were received during the year amounted to 25,204, white 23,195, negro 2,009 The admission rate for the white troops was 1,127 05, for the colored troops 915 88 The admission rate of the latter was smaller than that of the white troops in 1889, in 1892 and in the years following to the present time In speaking in my last annual report of their record of sickness, I characterized it as the most favorable yet shown by the statistics The same remark might be made concerning their record in 1895 Their admission rate for disease was 659 03, as compared with 852 99 among the whites, their rate for injury 256 84, as compared with 247 07, and the duration of each case was 10 5 days, as compared with 11 2 The number of men constantly sick per 1,000 of strength was 26 40 among the colored men, 34 54 among the white, while each colored soldier of the command lost 9 6 days on account of sickness during the year and each white soldier 12 6 days The rate of discharge for disability was 5 03 among the colored men, 9 51 among the whites, and the deaths 4 12 and 5 25, the deaths from disease being respectively 2 74 and 3 62 The susceptibility of the negro troops to disease was noted as greater than that of the whites only in the instances of rheumatism and neuralgia, although it was equal to or slightly in excess in several other diseases, as tonsillitis colic and constipation and conjunctivitis

Health of the military departments —The admission rate varied 798 32 in the Department of the Columbia to 1,355 63 in Texas It was above the army average only in the Departments of Texas, the East and the Platte The rate of constant sickness was highest in Texas The Departments of the Columbia, Dakota California and Colorado had low rates, the other departments did not differ much from the army average The Department of Texas had the worst record, the Department of the Columbia had probably the best, closely followed by the Departments of Dakota and of California

Four posts during the past year had admissions to sick report in excess of two entries per man These were Fort Myer, Va , with a rate of 2,800 00 per 1,000 of strength, Washington Barracks, D C , 2,137 74, Fort Slocum, Davis Island, N Y , 2,103 45, and Fort Ringgold, Texas, 2,078 21 Malarial infection was the principal cause of these high rates at the first two posts, but not at the other Five posts had the rate of non efficiency or constant sickness over 6 per cent of the strength Forts Brown, McIntosh and Ringgold, Texas with rates per 1,000 of strength respectively of 70 69, 64 05 and 63 92, Fort Myer, Va , 63 78, and Columbus Barracks, Ohio, 60 65 Washington Barracks, D C , although second in sequence of high admission rates, had a constant sickness of only 46 18, standing eleven in point of non efficiency while Fort Brown, Texas, although heading the list of non efficiency stands fourteenth in sequence of admissions

Six posts gave admission rates of less than 600 per 1,000 of strength Fort Yellowstone Wyo , 422 02, Alcatraz Island, Cal 461 54, Fort Wayne Mich , 484 62, Fort Porter, N Y , 515 62, Fort McPherson, Ga 566 14, and Fort Missoula, Mont , 578 75 Twelve posts reported a constant non efficiency of less than 2 per cent of the strength and among them were the posts of Plattsburg Barracks, N Y , Fort Wayne, Mich Fort Huachuca, Arizona, and Benicia Barracks Cal Fort Stanton, N M , had less than 1 per cent constantly sick, only 8 26 per 1,000 of strength

PREVALENCE OF SPECIAL DISEASES

Influenza prevailed to a somewhat greater extent than in 1894, 1,156 cases as compared with 875 The disease has continued since the close of the calendar year and [illegible] pected to form a notable part of the record of [illegible]

Diphtheria —Only a few cases occurred among the troops Several interesting reports on the use of antitoxin have been received The opinion of Army medical officers is decidedly favorable to its use as a prophylactic

Typhoid fever —One hundred and nine cases, 13 of which were fatal, were reported during the calendar year This is an improvement on the average annual prevalence and fatality of the preceding ten years, 138 5 cases, of which 19 2 per cent were fatal Of the cases during the past year, 12 per cent were fatal and the mortality per thousand of strength was 48 This latter rate can not be considered high, as it is exceeded by the typhoid mortality rate of most of our cities, notwithstanding the great susceptibility of soldiers on account of the predominance of young men in the ranks

On account of the uncertainty concerning the nature of the fevers reported from some of our western posts as Texas fever, continued fever, etc , a call was made from this office, Aug 30, 1895, on the medical officers of certain posts for a special study of the fevers during the season of prevalence Very excellent reports were rendered, but, as a rule, the assistance afforded by a careful microscopic study of the blood was not fully utilized in the differentiation of the cases

Malarial diseases —The admission rate for malarial diseases in 1895 was 82 56 per 1,000 of strength, and the rate of non efficiency 1 70, the former higher, the latter lower, than the corresponding rates for the previous year, 71 72 and 1 88 respectively, but both considerably lower than the average annual rates of the preceding decade, 103 32 and 2 57 The lowest admission rate on our records was reported in the calendar year 1891, 62 23, with a non efficiency of 1 58 Although some of the posts in New York, such as Fort Hamilton, Fort Wadsworth, Willets Point and West Point, contributed to the increased rates, the two posts on the Potomac River, Fort Myer, Va , and Washington Barracks, D C , were the main source of the increased rates, the former having 1,092 59 admissions and a non efficiency of 14 07 per 1,000 of strength and the latter, 1,079 89 and 13 71 Major Walter Reed Surgeon U S Army, investigated the character, prevalence and probable causation of the malarial fevers at these posts From a close study of the conditions, he came to the conclusion that in both instances the prevalence of the disease was due to the marsh lands of the Potomac valley

Diarrheal diseases —These diseases have been diminishing gradually in prevalence The admission rate was only 85 11 per 1,000 of strength, as compared with 91 77 during the preceding year and with 129 26 as the average annual rate of the preceding decade As a rule, the cases were trivial, the rate of non efficiency for the year having been only 78 per 1,000 of strength

Venereal diseases —The admission rate for venereal diseases, 73 72 during the calendar year 1895, was less than that of the preceding year, 80 43, and less than the average annual rate, 76 32, of the preceding decade The non efficiency associated with all these rates did not vary much, being a little over 5 per 1,000 of the strength The relative prevalence was greater among the whites than among the negroes, the admission rate of the latter having been only 52 26 In 1893 the admission rate of the colored troops fell below that of the white, and it has so continued since then

Alcoholism —The admission rate for alcoholism, 30 11 per 1,000 of strength is a slight improvement on that of the previous year, 30 94, but a great improvement in the average annual rate, 44 20, of the preceding decade The rate of the colored troops was, as usual, low, 6 17

Rheumatic affections —The admission rate was somewhat larger in 1895 than in the previous year, 64 08 per 1,000 of strength, as compared with 63 33, but the discharges for disability numbered only 12 as compared with 21 The improvement in the health of the troops of late years may be seen by comparing these figures with the average annual admission rate of the decade 1884-93, 83 34 with 55 2 discharges for disability

Tuberculosis of the lungs The rates for tuberculosis of the lungs were smaller this year than last Admission 2 42 discharge 1 06, death 37, as compared with 2 96, 1 59 and 61 They are considerably smaller than those of previous years, for the prevalence of consumption among the members of the Indian companies gave high rates as the [illegible] he previous decade It is to be noted also that [illegible] st two years the rates [illegible] mong th [illegible] ave fallen so as to [illegible] fc formerly they

Injuries —T[illegible] than in 1894 when [illegible] average annual ra[illegible] the relative r no corresponding increase in their severity, for the non efficiency, 8 46, was somewhat less than that of the decade cited

Nineteen cases of suicide were reported, as compared with 18 during the previous year

Radical cure of hernia —In September, 1895, after considering fully the results attained by surgical treatment in the radical cure of hernia, together with the small amount of risk involved in the operation as now conducted under careful aseptic supervision, I came to the conclusion that the operation might be made available to preserve good soldiers, although ruptured, in the service and to lessen the number of men discharged for disability and subsequently pensioned for hernia The annual loss of men by rupture has always been considerable During the six calendar years ending Dec 31, 1894, 153 men were discharged I did not consider that the progress of surgery warranted a resort to operative proceedings in all cases, but felt confident that surgical interference would enable many to continue in the military service, or earn their livelihood with comfort in civil life, who are now discharged and pensioned for hernia

Since September, 1895, twenty nine cases of hernia have been treated by operation with the most satisfactory results so far as can be determined at this early date This gives an excellent promise of future benefit in cases that have been hitherto regarded as disqualified permantly for military service

THE SANITARY CONDITION OF THE ARMY

Quarters —In four instances during the course of the year attention was specially invited by medical officers to the insanitary and generally worthless condition of the barrack buildings at their posts The barracks at Fort Preble, Maine, were characterized as very old and not worth repairing At Fort Custer, Montana, the barracks with one exception are old and dilapidated, all the floors uneven, worn through in places, and so near the ground that the subfloor space can not be cleaned nor inspected except by taking up the floor The dilapidated condition of the buildings at Whipple Barracks, Arizona, has been reported on various occasions They are overcrowded, draughty and poorly ventilated Estimates for additions to relieve the overcrowding have been disapproved In July and August, 1895, the improvement of this post was again discussed and urged strongly by the Chief Surgeon, in the hope that early and favorable action would be taken by the War Department

The marked improvement that has been made during the past few years in the sanitary condition of our military posts, is specially manifest in the fact that during the past year no report was received concerning the crowded condition of prison rooms or guard houses, nor concerning the want of ventilation or repair of the buildings occupied for prison purposes Formerly unfavorable criticism on the quarters provided for men under guard was as common as it is now infrequent

Drainage and sewerage —At the large and important post of Fort Meade, S D, privy pits are still in use, a suitable sewerage system will no doubt be considered with the reconstruction of this post The privy pits at Fort Keogh, Montana, also should be filled up, and replaced by the dry earth system until sewers are built

Concerning the efficiency of the dry earth system there is ample testimony from the experience of many military posts Where complaint is made there is found on investigation to be some want of the necessary care in carrying out the details of the method As an instance in point, it was reported of one post during the year that "in only one closet was any dry earth found, and in that no evidence of its systematic use" The action taken by the post commander on this report was to call the attention of company commanders to this negligence and on his next inspection the surgeon found the dry earth closets in satisfactory condition

Water —A temporary scarcity of water was reported from several posts, as Fort Canby, Columbus Barracks, Fort Grant and Fort Monroe The bad quality of the river waters used at certain posts, as Jefferson Barracks, Fort Leavenworth and Fort Custer, was specially noted by medical officers, who recommended filtration for their purification The Las Moras Spring at Fort Clark appears now to be protected from inflow of surface water The discovery of a spring at Fort Reno furnishing a water similar to that of Caddo Springs, will greatly benefit that post There has been much activity during the year in improving the water supplies of military posts Medical officers take special interest in the subject, and the Quartermaster's Department has carried into effect many suggestions for extension and improvement

Food —The food of the men has been reported almost uniformly as ample in quantity, of excellent quality, and well cooked

Clothing —In my last annual report I had occasion to invite attention to adverse criticism by certain medical officers on the quality of the leather in the shoes issued to the troops No such criticism is found in the reports of the present year, yet in one instance a number of men were disabled on a practice march by abrasions and inflammations of the feet, attributed to ill fitting shoes The shoe now furnished by the Quartermaster's Department appears to be of excellent quality, make and shape, and there seems to be no reason why men should be disabled on a practice march if proper care is taken in having their shoes adapted to the feet before the march is undertaken Men who begin a practice march simultaneously with the process of breaking in a pair of new shoes, are likely to suffer from chafings or undue pressure, which may disable them temporarily and unnecessarily

The various articles of clothing have been of good quality, and suitable to the climate and service

Habits of the men —The remarks on sanitary reports concerning the habits of the men are generally satisfactory, and are corroborated by the lessened rates of the past year for venereal diseases and alcoholism

Facilities for personal cleanliness have been greatly improved at our military posts during the past few years At present they are rarely referred to as inadequate

Gymnastic training and athletic sports are held responsible by many medical officers for the increase in the number of injuries during the past year Their view is no doubt correct, but since the increase was not manifested in the rate of non-efficiency it is evident that the extra cases which raised the admission rate above the average of the preceding decade, were not of a severe character The accidents of the gymnasium and the athletic field are offset by the benefits derived from the training Men are drawn away from vicious habits which tend to increase the sick list, and the ability of the system to withstand harmful influences is greatly increased Hence, although the list of injuries is enlarged by the practice of athletics, the rates of disability from injury and disease are less than in previous year in the history of our Army

Respectfully submitted, GEORGE M STERNBERG
HON D S LAMONT, Surgeon General, U S Army.
Secretary of War

SELECTIONS

Serum therapy —A fermentation has been going on in medicine for the last century, as a sign of which the systems in rotation appear on the surface and after a longer or shorter length of time disappear to, who knows at what future date, start the game anew The present is the age of serum therapy. About a hundred years ago the "humores" also reigned, although in a different way Humoral pathology, which supposed the seat of disease to be in the fluid constituents of the body, was suddenly replaced by cellular pathology The microscope taught us that the tissues consisted of cells which to a certain degree were independent organisms and upon whose *functions depended the fate of the entire organic* structure But as no footing could be found in the cellular pathology, the research was continued in other directions

On the one hand there developed by the aid of botany and chemistry a modern scientific pharmacology, while on the other side pharmacologic remedies were entirely discredited This led to the formation of the nihilistic school, which at least had the advantage of making unprejudiced observations

The development of the physiology of to day has led us, at the instance of the discovered normal and diseased functions, to judge the therapy of the latter quite different It was the development of a new physiologic school But now again the microscope discovered new things, bacteria, bacilli, microbes, and instantly all diseases were ascribed to these microorganisms The next step was for chemistry to appear on the scene with microbe killing remedies, and as it at the same time furnished a few new analgesics and febrifuges a temporary armistice was secured The observation, however, that it was not the microbes as much as their poisonous products that were in question, soon again aroused those who would rest on their laurels Chemistry was combined with bacteriology to solve the enigma by isolating the poisonous products and experimenting with these. This led to their inoculation, as it appeared that these products were poisons for the microbes themselves, as for instance alcohol and yeast enzyme. According to this scheme tuberculin was inoculated a few years ago. The danger of this inoculation, however, soon showed the fallacy of the theory, and investigators sought after a perfection of the idea. As the latest result of their efforts we have the serum treatment. Serum therapy can only be understood when we follow the train of thought which lies at the base of inoculation.

As an original form of vaccinating there was prevalent in China and India direct transmission by injecting pock virus. In place of this, clothing used by smallpox patients was sometimes worn so that at an opportune time they might also pass through the disease, probably during a light epidemic, as in those days smallpox was considered as measles and scarlet fever are to day, which according to our mothers and grandmothers every child must have had.

Vaccination also came into practice by reason of its serving as a quietus for those mothers who had to send their sons to India, being thereby enabled to nurse them at home, instead of having them plague stricken in a foreign clime. But as inoculation of pock virus demanded too many victims, surgeon Jenner conceived the idea of inoculating cowpox, which he considered transmitted smallpox. As this vaccination in comparison to the former inoculation was comparatively harmless, it soon gained favor and still continues so, although no explanatory theory was then advanced or ever since given, and in spite of being contrary to all modern laws of antisepsis.

One could imagine, and this many an adherent of the vaccination theory does to his own satisfaction, that as a rule a person gets measles and scarlet fever but once, this would be applicable to all infectious diseases and especially to smallpox. In reality this is neither the case in smallpox, diphtheria nor any other disease. However, following this supposition it has been said that, having had smallpox, protects from smallpox, and further that passing through a mild form of pox, that is vaccination, also gives the desired protection. After the word "protects" was unobservedly smuggled in, nothing remained to be proven, and up to the present day the votaries of vaccination have owed us a satisfactory explanation.

In every falsehood there is, however, contained a kernel of truth. If we will, namely, observe more frequently that during the existence of a febrile disease, the afflicted one is not susceptible of other infectious diseases, as owing to the increased vital activity, increased oxidation etc., a second attack is more easily warded off, we can also admit that an artificially produced febrile reactionary condition as is produced by vaccination will give a certain protection for a short time. This protection can, however, not last longer than a few weeks, it will therefore be seen why sober observers recommend the unusual repetition of vaccination. The principle of vaccination, however, was established and has held its own alongside of all change of theories. In the course of time, all possible kinds of vaccinations patterned after both "inoculation" and the "moderated vaccination" have been tried. But syphilis inoculation as well as cholera, hydrophobia and other vaccinations were soon abandoned. The same fate was shared by the tuberculin inoculation, as they all did notoriously more harm than good.

Research was continued, but this time from the only correct standpoint why certain persons were immune, i. e., proof against contagion. These individuals, whether man or beast, must contain within themselves a protection. This protection could be found only in the fluid tissues, the all permeating blood, as the different tissues are too dissimilar to contain protective matter. The theory was advanced that serum, the blood fluid of an animal which had overcome an infection, as for instance diphtheria inoculation, should be injected into other animals in the supposition that the serum contained a contra poison, an antitoxin. This is Behring's serum therapy. According to my notion we again have one foot in the too readily discarded humoral pathology, and I can only express my rejoicing at this, as there is more contained in a humoral pathology modified according to our latest physiologic and chemic knowledge than many a one would dream. We will accept as undoubtedly correctly observed the fact that the injected serum of an animal having survived an infection gives a certain protection to another animal or in other words puts it in a better condition to withstand infection. We, however, lack conclusive evidence, whether so large a quantity of serum (about 1 gram to 1 kilo body weight) of a healthy, unprepared animal is also capable of producing this so called immunity in an infected one. It can be admitted that the addition of so large a quantity of serum, an excellent nutrient fluid, awakens, that is, strengthens the vital energy to such a degree that the weaker organism acquires the ability of the naturally immunized one to conquer the intoxication. The blood has so many chemic and physical properties, the body so many protective contrivances, such as fever, etc., that one can not make an apodictic assertion as regards antitoxins or counter poisons. Professor Buchner (Munich) has proven by experiments on animals that antitoxins are altogether out of question, as the chemic quality of the animals experimented on has an important bearing on the case. The originally immune animal can not possess any antitoxin, beside during the course of an infectious disease a number of reactions take place which tend to make the introduced injuriousness harmless. In this regard Buchner's principles may eventually play an important part. But even admitted that Behring's theory is correct, what good is it? They claim the mortality to have dropped from 50 per cent. to 25 per cent. in diphtheria. Admitting the correctness of the statistic observations I still find the rate of mortality so high that I would hardly venture to use it as an argument. Beside it is openly admitted that where, as there usually are in severe cases, streptococci are present these cases are not affected by the serum. Well, in the milder cases I use no other remedies but those I have explained in my treatise[1] years ago and which we more or less all use. In severe cases I really need no assistance either, besides such an assistance is made directly impossible by the antitoxin treatment. We can, therefore, not use this kind of serum therapy. The contagionists have repeatedly stated: "Live as you please, only be sure to get vaccinated in the opportune moment." This is surely not according to the laws of hygiene. Consequently serum therapy is no hygienic triumph. Undoubtedly, and we should not be misled by this, the serum therapy will be longer lived than any previous inoculation method, as it is relatively harmless. But the lack of success will ultimately kill it off.

Those who know what weapons have been employed to conquer diphtheria, will also lend a willing ear to the objections of those skeptics who attribute the lower rate of mortality in diphtheria under the serum treatment, to the absence of the old drug poisons. Add to this, better nursing and the possibility of the serum being a blood nutrient, and why should there not be good results?

We likewise obtained good results during the first period of tuberculin inoculation, because the patient's appetite was no longer impaired by giving creosote and the "interesting cases" were better nursed. If we start with the principle that the healthy organism contains a protection, probably protection matter and possibly antitoxins, then the only sensible thing to do is to investigate the protective power and by correcting the mode of living and the like and to impart it to those individuals who on account of want of natural protection are in need of it. This is the opinion of the individualists who find within the quality of the individual the riddle which is being tried to be solved without

---

[1] Die wichtigsten Kapitel der natürlichen Heilweise. Stuttgart. Zimmer's Verlag.

I think there are animals and human beings who are relatively immune against all infections Against certain poisons they are positively proof, others by means of chemic and physiologic protection contrivances, they conquer We can impossibly vaccinate against all infectious diseases from the beginning, that means to vaccinate the sucklings Furthermore, we can at the decisive moment, that means in case of sickness, only vaccinate in the culture centers against all possible attack, presupposed we had "antitoxins" for every disease, but so far we only have the diphtheria and tetanus antitoxins, of which the latter has proved itself useless (Relatively speaking, in the meantime barring other therapeutics, people would have to keep on dying for years, as it would take that long before all the antitoxins would be discovered) It is moreover uncertain whether great damage is not done the body by inoculating various antitoxins, which according to Buchner are toxin derivatives and related to the toxalbumins

On one hand we do not care to wait so long, on the other we must go to work with more logic, expecting nothing from uncertain remedies, but aspire to acquaint ourselves with the relatively universal immunity and its conditions That the universal immunity is not sparingly distributed among human kind is proven by the mere existence and constant increase of humanity, which in spite of thousands of years of aggression by all possible plagues has held its own and, as it appears, has acquired a natural immunity against pestilence, typhoid and smallpox

In this field of natural immunity by leading a hygienic life have I and others, in theory and practice, rendered such service that we have therapeutically gained such an ascendancy over the votaries of serum therapy, who not until now—and that in the wrong light—have taken the individual into consideration so that a better hygiene and therapy than we have against infectious diseases can not be found anywhere to day I do not wish to cite statistics, but on request any physician of our school will stand ready to treat diphtheria cases under control with a smaller resulting mortality rate than can be obtained by means of the so called serum therapy It is our object to make *our own* serum of the best possible kind and quality

Presupposing that my doctrine of dietetic blood diathesis[*] is well known, we have in it a lesson which if applied to our diet and mode of living, will bring the protective power of *our* serum to its normal height, *i e* , will make us relatively immune The quintessence of our doctrine is the proof that the reduced alkalinity of the blood of civilized men can by dietetic means be brought back to its normal strength According to Von Fodor and others the degree of alkalescence of the blood is proportionate to its immunizing power, which experimentally proves the correctness of my views on serum therapy While in a case of mixed diphtheria with streptococci the physician applying diphtheria antitoxin is helpless, the organism made relatively immune by means of dietetics is able by way of its innate protective power assisted by appropriate external remedies to successfully combat such cases

For the forgoing reasons I have no fear in my own behalf in acute diseases such as diphtheria for instance, as I know the quality of my body and its serum Not so with others whom we know to be filled with autotoxins, as the cause of the disease, be it organized ferment, a microbe or a chemic ferment, an enzyme liberates them For the body of the majority of the population, who are governed by false dietetics, is overloaded with insufficiently assimilated albumin and insufficiently oxydized substances which by contact are doubtlessly changed into toxalbumins (Compare Ernest Krauss in *Zeitschrift für physicalische Chemie*, Band xviii, Heft 2 "Über die Ausnutzung der Eiweissstoffe in der Nahrung in ihrer Abhängigkeit von der Zusammensetzung der Nahrungsmittel ") Krauss proves that where albumin is freely taken as nourishment, only part of the albumin is changed into peptone, the other part decaying in the bowels, "by which on account of the presence of a large quantity of decayed matter the body is only injured "

Upon the chemic condition of the body, not upon the amount of infection depends the severity of the case The microbes do not easily gain access to the inner body, but the toxins do, which doubtless, being relatives of the enzymes, are also capable of developing results like these They furnish us with new dissecting matter, that is, loosen the vital process (fever and oxydizing), the deposited decayed matter, autotoxins in the real sense of the word With the autotoxins lies the danger They injure the heart and the kidneys and do harm, when that little diphtheritic toxin has long been made harmless

It is interesting to note that Professor Escherich (Graz) in No 22 of the *Wiener klinische Wochenschrift* presents the following theses covering my views

1 For the appearance of diphtheritic disease there is necessary, beside the bacillus and the possibility of its invasion, a specific receptiveness of the organism about to be infected

2 The condition of the local and general disposition, the greater or less degree of virulence of the bacillus, the latter only secondarily considered, are a criterion for the termination of the case

3 Also other and even saprophytic bacteria, besides their products, may have an effect on the spreading and the clinic termination of the process

I consider the third thesis a circumlocution of what I understand by autotoxin My therapy in diphtheria is therefore primarily aimed to put out of the way the autotoxins The evacuation of the lower gut by means of injections furnishes to us in ninety cases out of one hundred such a terribly smelling stool which differs distinctively from other fever stools, which are usually dry and not so fusty, this being my reason for thinking that diphtheria is a general instead of a local disease, as now supposed

By these means, at least, dangerous products of decay are prevented from being absorbed The next thing for us to do is to remove the autotoxins by means of increased perspiration and eventual transpiration, by reason of which long lasting partial or entire packing, eventually sweat packing, are brought into question By increasing perspiration and transpiration, the almost constant relative hydremia is done away with

Finally, for nutrition we will not choose albumins, as these, under the conditions, would be the same as poison Moreover, we will introduce into the serum the mineral substances, nourishing salts in the shape of readily assimilable fruit juices and lemonades, and keep the body with the sugar and water of them in a sufficiently nourishing condition, without especially burdening the gut

That is my position toward serum therapy Behring's serum therapy is a very interesting scientific problem Therapeutically considered it represents a byway which, on having recognized the truth that our own serum should and will solve the problem, as a rule comes too late to be of any service to the patient — Read before the Congress of Physicians at Nurnberg (Germany), by H Lahmann, M D Translated by Carl Strueh, M D , Chicago

Morphin Antidote to Cyanid of Potassium —Heim discovered recently in the course of some experiments that animals which had received a fatal dose of potassium cyanid were saved by the injection of a non fatal dose of hydrochlorate of morphin This effect seems paradoxical, as the two substances combined in the laboratory produce only a precipitate of pure morphin and the elimination of free hydrocyanic acid — *Semaine Méd* , September 23

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association Dr Henry P Newman, Venetian Building, Chicago Ill sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character intended for publication in the JOURNAL should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL proof sheets returned or in regard to subscriptions should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION 61 Market Street (*Occidental Buildings*) *Chicago*

Original communications are only received with the understanding

or re-integratively upon the visual substances, is against all known chemic or physical laws It is hard to understand how the diminution of all rays can cause an increase of the "black" rays There is also difficulty in conceiving the existence in the same space of three different chemic substances that change, not only singly but two or three together, under the influence of the light rays received, and do this in two different ways, assimilatively and dissimilatively.

Finally, neither of the two theories is satisfactory in explaining the union of the different primary color substances into the complex ones, red and yellow or red and blue, for example

In order to meet these difficulties he points out, TSCHIRIEW offers a theory of his own In the first place he accepts MUELLER'S law of specific energies in a rather wider sense than has been hitherto admitted, allowing variations in quality in the homogeneous sensations derived from a single excitation of it did not sufficiently suggest the possibility of failures of color perception not dependent directly on its defects. Men have written on the color sense as if consciousness extended down to the peripheral termination of the optic nerve, or perhaps it should be better stated, as if color perception there took place. HELMHOLTZ, HERING, TSCHIRIEW, FICK, or any other theorizers on this subject have really only the task of producing a hypothesis that will account for the phenomena under normal conditions of the higher visual centers, the derangements of these latter afford an unknown, but certainly extensive, range of possibilities of morbid alterations or defects of the color sense.

The theories of the author here quoted may not be altogether new, indeed, it appears possible some of them may have been emitted before, but they are in their way suggestive and noteworthy. His paper contains some other points worthy of mention, such as his statement that white as a sensation is not the result of the blending of all the spectral colors but is simply the effect of the reflection of uncolored light by minute particles under certain special conditions. It is one of the suggestive contributions to the literature of the subject, whatever may be the ultimate estimate of the views it presents.

LAY DISTRUST AND ENMITY OF THE MEDICAL PROFESSION

For two thousand years or more the medical profession has waged a ceaseless war to obtain the fundamental condition of medical knowledge and progress, *i e*, dissection material, and to-day many medical colleges are compelled to import from long distances and at a crippling expense an insufficiency of cadavers.

Ever since the rise of the scientific spirit in modern times the use of animals for experimentation, quite as necessary a prerequisite of medical progress, has been bitterly and violently opposed by the non-medical world, and to day that opposition is more dogmatic and furious than ever.

The lay world, as regards both private individuals and governments, is so indifferent to or suspicious of us that while endowments, scholarships, etc, running into millions exist for the encouragement of the study of languages, astronomy, theology, etc, yet medical education and medical students are left solely to self-interest, with almost no endowments to help what is the first necessity of human life—health and the eradication of disease.

The one benefit of most proved and patent service to humanity, which medicine has given the world—vaccination—finds everywhere, but especially in England and America, thousands of bitter opponents. One of these in a speech in England as regards the recent Gloucester epidemic where hundreds sacrificed their lives to the craze, has the audacity to utter the following words: "Gloucester presented circumstances and cases which proved undeniably that vaccination was nothing but a delusion and a snare and that insanitation was the real tap-root of the whole of the sufferings of that poor, miserable, devoted city. During the panic the doctors had been piling on the agony and pocketing the plunder and scattering people through the length and breadth of the country with their arms in slings as if they had just returned from a great European war."

Lastly, the opinion of the lay world is made still more plain by the facts of the oceans of "patent" or secret nostrums eagerly bought and devoured by it, by the long struggle, still going on, to obtain medical practice legislation to root out quackery, and by the avidity with which it supports medical sectarianism and quackery in the regular profession.

Such facts as these might be multiplied indefinitely.

Upon the other hand, every intelligent physician has the sincerest and most well-grounded conviction and consciousness that the profession taken as a whole is more unselfishly and more successfully devoted to the alleviation of suffering—of the very people (and their children) who hate that profession—than any single body of men of so large numbers the world has ever seen.

All this being true, one is almost disheartened at the ingratitude, the stupidity and the brutality of our enemies. Why labor for a united world that scorns the help and hates the helper, blind and ignorant of its own true need and inobservant of its best friend? Beyond a doubt it is the recognition of this very fact of the combination of ignorance and need of the world that sustains the devotion to duty of many physicians and keeps them from joining the ranks of the shrewd self-seekers. The poor victims of their own hate and egotism and ignorance are of course too pitiable to be either duped or detested. They are in truth pathologic specimens of society and history, and a man with any largeness of character can not upbraid or punish or despise a bit of morbid tissue, whether sealed in alcohol or washed up in the world's sewage. The cold-blooded will study it and philosophize about it, the warm-blooded will commiserate, and both will regret the disease and malignity that produced it and smile lukewarmly at the passion which fires the hearts of the monomaniacs.

Two things remain to prevent despair. The first is that we are gaining, slowly perhaps but still surely, in our warfare against disease and ignorance as the lessening death rate certainly shows, and secondly, a progressively increasing number are recognizing that the acceptance of the selfish and personal end would bring no added happiness. We are winning more and better allies in the lay world, and the insatisfaction of a wholly greedy life is becoming always more evident to a larger number of physicians. When struck by some particularly ugly fact—some triumph of quackery, some victory of a blatant or sly self-advertiser over honesty and modesty—we may be tempted to cry, "It's no use! We might as well give up!" But a large and healthy outlook and overlook will at last convince that there is a decided and clear measure of progress being secured with every generation's passing.

The puzzling fact remains to challenge our ingenuity. Why this persistent opposition? Viewed simply as a psychologic riddle we can not help being struck by the incongruous and egregrious blundering of the lay world in so hating the profession which is seeking only the good of the hater. Why this century-long bitterness and malignity of spirit, reaching even to ludicrousness in the diatribe of the poor fellow who charges the doctors with "pocketing the plunder," the fees for vaccination from the be-pested Gloucester folk. To take another instance, doubtless many anti-vivisectionists are in reality tender-hearted people, but doubtless also many are spurred to their violence not by pity of the "victim," but by hatred of the "vivisectionist." Macaulay said that the Puritans opposed bear-dancing, not out of pity for the animal, but because it gave pleasure to the spectator. In every one of *Life's* cartoons or silly lunges on the subject of vivisection one sees that the bitterness of spirit against physicians is many times stronger than any sentiment aroused by the sufferings of the animal.

After all deductions are made on account of inherited love of magic and miracle-mongering, one is finally driven to believe that the fundamental cause of the hatred of Lord Omnes for us is due to his utter inability to realize that men can have any abiding motive of conduct that is not in its last analysis selfish. He knows in his own heart that if he were a physician he would practice vaccination, not for the good it would do, but because of the fee he should derive from performing the operation. According to his philosophy the preacher makes better wages and with less labor by preaching than he could by business or farming or shoveling, and so with the rest of the "parasites." Feeling that such are his own ethical standards, he must believe they are also those of all others, and the half-hidden consciousness that it is not so with these others arouses in his own heart a tempest of passion to keep the voice of conscience from being heard. Then, too, we have in every city and town self-advertisers, quacks within the profession, whose trickeries are so manifest as to strike the attention of all, and seeing these the profession-hater sticks his tongue in his cheek and gloats over the supposed fact that this particular charlatan, as he thinks only exposes what the others are more shrewd in hiding, and that at last, if it were known, w [illegible] "all alike [illegible]

And thus it comes to the moral, that there [illegible] enemy so harmful to the profession as the one within our own ranks who hypocritically pretending acceptance of the higher standards of conduct of the guild, in reality practices the greeds, charlatanism, and self-seeking.

EMPIRICISM VS. WORKING HYPOTHESES IN THERAPEUTICS.

The excuse most strongly advanced by the charlatan for his existence is the specious one that therapeutic discoveries are all the results of chance empiricism. This plea is reiterated by physicians whose mental indolence limits them to what are most absurdly called the "practical" (but more properly the "receipt book") side of medicine, just now exploited at the expense of the profession, by certain advertising Hahnemanniac "free doctors." The shallowness of the scientific foundation of the "receipt book doctrine" contrasts markedly with its wide acceptance. Many physicians fail to recognize the great truth pointed out by Claude Bernard that, "All natural philosophy is summed up in this: To know the law which governs phenomena. The experimental problem reduces itself to this: To foresee and direct phenomena. It will not satisfy the experimental physician, though it may the merely empirical one, to know that quinin cures ague. The essential thing is to know what ague is and to understand the mechanism by which quinin cures. All this is of the greatest importance to the experimental physician, for as soon as he knows it positively, the fact that quinin cures ague will no longer be an isolated and empirical fact. This fact will be connected then with the conditions which bind it to other phenomena and we shall be thus led to the knowledge of the laws of the organism and to the possibility of regulating their manifestations. A striking example can be quoted in the case of scabies. To-day the cause of this disease is known and determined experimentally, the whole subject has become scientific and empiricism has disappeared. A cure is surely and without exception effected when the patient is placed in the condition known to produce this end. This is the purpose of physiology and medicine, to make oneself master of life, in order to be able to direct it." Even the briefest examination demonstrates that therapeutic discoveries were never made by chance empiricism, but that all result from working hypotheses which though often fetichistic in origin had excellent results. One excellent *illustration is the famous* doctrine of signatures, which though badly abused from forced interpretation, strongly stimula [illegible] search. One most [illegible] idence of the ority of even fetic [illegible] eses t [illegible] emp [illegible] sm is the p [illegible] (f [illegible] e Aryan [illegible] nts ing to Greek myth, was fed on honey from the sacred ash and from bees. Among the ancient Germans that sacred food was the first put to the lips of the newborn babe. So it was among the Hindus as appears from a passage in one of their sacred books. The father puts his mouth to the right ear of the newborn babe and murmurs three times, "Speech, speech." Then he gives it a name. Then he mixes clotted milk, ash and bee honey and butter, and feeds the babe with it out of pure gold. In the Highlands of Scotland at the birth of an infant the nurse takes a green stick of ash, one end of which she puts into the fire and while it is burning, receives in a spoon the sap that oozes from the other, which she administrates to the child as its first food. Some thousands of years ago the ancestors of this Highland nurse had known the *fraxinus ornus* in Arya (KELLY, Indo-European Folk-lore) and now their descendant, imitating their practice in the cold North but totally ignorant of its true meaning, puts the nauseous sap of her native ash into the mouth of her hapless charge. The old crones who haunt the obstetric chamber often practice these antique methods of warding off evil spirits, or, as the crones would phrase it, preventing bad luck. The laxative quality of ash honey evinced the beneficent fetichistic effect of the drug, since, according to a folklore principle (still accepted by certain races), constipation is one of the means "whereby the devil worketh," to quote BAXTER, the seventeenth century Puritan. Because of the tendency of fetichistic explanation to vanish with advance in culture, the original working hypothesis (on which manna was given) disappeared to give place to the purely laxative principle. This slow development of a humble laxative from the awe-inspiring sacred ash (the Ygdrasil of Scandinavian mythology) significantly demonstrates that even the slightest scientific discovery is not suddenly made, but is the product of a long evolution whereby, as SHELLEY sings:

> "Thought by thought is piled till some great truth
> Is loosened and the nations echo round."

The physician who fails to recognize the great truth here enunciated aids the quack who pretends to discover stolen and distorted ancient therapeusis.

SOCIAL STATUS OF THE BRITISH MEDICAL PROFESSION

The completion of the sixtieth year of Queen Victoria's reign will doubtless be marked by the usual anniversary creation of peers, baronets, knights, etc. At present it seems probable that, as usual, the British medical profession will compete with fertilizer and sausage manufacturers for baronetcies and knighthood but will not dare to rival the lordly distillers and brewers in the race for peerages. The British medical profession, during the present century, far from occupying a high social status, has always been viewed askance by the present Queen and her uncles. It disproved the foul calumny, unworthy even a village gossip, which the court clique launched against the Queen's unfortunate maid of honor, Lady FLORA HASTINGS, whose sarcomatous uterus was proclaimed by highest authority evidence of unchastity. The bitterness with which most of the WETTINS regard the medical profession was voiced by that master of billingsgate, the Duke of Cambridge, when the British army medical service was given a definite status, a reform struggled for by almost all that is illustrious in nineteenth century British literature and science. The Duke thus addressed the surgeon-general of the army whom he met at a dinner soon after it had been decided by the government to give official rank to members of the medical department:

"Good evening, Surgeon-General, or Field Marshal, or what the —— they call you now, I don't know how to address you, you with your new titles, I don't know what the —— I am myself, I suppose you expect me to take my —— hat off to you, what —— do you —— fellows want?"

This view of the British profession is so accepted by the snobocracy that the Duke of Westminster will not let residences on certain London streets to "medical men or other minor tradesmen." The sixtieth anniversary of VICTORIA's reign seems a good time to raise the social status of British medical men by the creation of medical peers. It should be remembered in this connection that one of the greatest families of the present period traces its recent ancestry to a surgeon-apothecary, HUGH SMITHSON. He, a century ago, on marrying the peeress of the PERCYS, was created Duke of Northumberland in 1766. It was suggested that his ducal coronet bear senna leaves in lieu of the usual strawberry foliage. The English peerage marks social status in Great Britain. There is no reason why, in view of the regard shown physics in the peerage of Lord KELVIN, medical science should not be equally recognized. The House of Lords of the "crowned republic" could with advantage bulwark itself by medical members against the rising tide of democracy.

CORRESPONDENCE

Paracelsus

CHICAGO, Oct. 19, 1896.

To the Editor:—On page 879 of THE JOURNAL is a clipping which presents the life and character of Paracelsus in somewhat too roseate a hue. When I was at Salzburg in 1889, admiring the quaint picturesqueness of the town, reviving memories of Mozart and wondering at the modern troglodytes residing in furnished apartments cut cave like out of the solid rock in the hillside, I naturally, as a physician, hunted up the relics of Paracelsus. The monument and chapel described in the clipping are easily discovered. Of much more interest to me, however, was the home of this curious character. At one end of the Salzach bridge and within hailing distance of the home of Mozart, stands upon a projecting corner, facing a kind of little square, a plain, flat, unornamental four storied house, with a large portrait and explanatory plate in regard to Paracelsus on the front of it This was the last residence of the erratic, wandering, doubtful quack and genius Even his name is in doubt Some say it was Aureolus Philip Theophrastus Bombast de Hohenheim, others declare that it was only Philip Aureolus Theophrastus, while the Bombast part of it belonged to his father Paracelsus, which is an atrocious Greco Latin rendition of his patronymic, is good enough, I trust, for us Amidee Latour was fond of giving some such advice as this Remember always to appear to be doing some thing—especially when you are doing nothing Paracelsus understood this principle most effectively, and coming upon a time for which his peculiar talent was most fitted, he enjoyed a tremendous success He seems, in fact, to have been an intellectual giant, apparently doing everything, when in reality he was doing nothing Irascible, eccentric, fond of trickery, a liar, a charlatan and a quack, a man of undoubted genius with a few really valuable and practical ideas, a glutton, drunkard and common scold, a visionary, an absurd theorizer and a shiftless wanderer, he nevertheless impressed so forcibly the age in which he lived that, to the present day his renown is considerable Bombast was not a bad name for him He was born near Zurich some time time about 1493 He never attended any regular school, but was taught some Latin by his father, who was a physician Then he began to travel, or rather roam about, probably like Goldsmith, supporting himself doing odd jobs and amusing the people with his necromancy From the back of a cart he may already have begun doling out his sure cures to a gullible and voracious public He was somewhat of a chemist and, like many other learned fools of that foolish time, toiled night and day in search of the mythic philosopher's stone Think of the man at 33, boasting of having cured some thirteen princes, all given up, of course, as incurable by the doctors The world flocked to him and he waxed rich When a man lies why shouldn't he do it thoroughly? says the quack Thoroughness is always commendable The public, "Dear old Grandam" De Quincey calls it, fairly dotes upon a liar Well, the boasting of Paracelsus paid him munificently He was appointed professor of something in the University of Basel, and at once began creating a disturbance He said "reading never made a physician," and so he publicly burned the books of Galen "Countries are the leaves of nature's code of laws—patients his only books" About this time medicine was overrun and worm eaten with theorists, spiritualists, humoralists, materialists and all the rest of that ilk, and the turning of the world's gaze back upon nature was really one notable thing done by this grand charlatan—a thing almost good enough to atone for his outrageous falsehoods and cheats Even to day a Paracelsus might do some good work in certain quarters Finally a climax was reached in Basel Some grand dignitary whom, as usual, he proclaimed to have cured, refused to settle the little matter of the bill The dignitary controlled too many wires for the irascible professor, notwithstanding his mythic thirteen princes, and so one cheerless day the latter packed up his alembics, retorts, manuscripts, bones, tobacco pouch and whisky flask and resumed his peregrinations Like an unwelcome fowl in an old well regulated farmyard, he created an uproar wherever he went The "profession" of that day was synonymous with blind conservatism and obstinate unprogressiveness, and naturally it could not have been expected to fondle this noisy upstart who laughed at all its pet notions and burned its ponderous tomes At last he arrived at Salzburg and was given a most comfortable domicile by one of his admiring dupes He began quarreling as usual with the local profession, and ended by being "pitched out of the window of an inn by the doctor's servants and had his neck broken by the fall" Thus ended the strange career of this meddler in old established customs Both his life and his teachings were an incoherent medley He started medicine upon a new tack when he turned its eyes upon the doings of nature and away from the moth eaten volumes of useless libraries, but in so doing he intermingled much bosh, nonsense, fraud, miserable deception and falsehood He is dead, however, and may heaven rest his bones more peacefully there beside the blue Salzach river, than he did those of his poor patients whom he cajoled into swallowing his nauseous decoctions Like the worthy doctor to whom the immortal Gil Blas once served as assistant, he had one system for all his patients, and was a diligent bookkeeper, so to speak, for the next world

L Harrison Mettler, M D

Medical Expert Testimony

Dannemora, N Y, Oct 15, 1896

To the Editor —I have been very much interested in the papers and discussions published in our Journal relative to medical expert testimony As chairman of the committee appointed in February, 1895, by the Medical Society of the State of New York, to report upon the most feasible plan for improvement in methods of obtaining medical expert testimony, I presented to the committee two reports in January, 1896, the one which was adopted both by the committee and the society being that practically incorporated in the Bill presented by Dr Suiter, and already published in our Journal The one which the committee, while favoring the method, thought inadvisable to present to the Society fearing that it would meet with opposition, was as follows

> *Resolved*, That the Medical Society of the State of New York would recommend the enactment of a law by the legislature providing for the appointment of experts by the courts, and that only physicians of repute and holding a certificate of qualification as hereinafter defined in the particular branch of medical science to which the question calling for expert opinion relates shall be appointed
>
> The above named certificate of qualification to be issued by the Board of Regents, and duly filed in the County Clerk's office of the County in which the holder of such certificate is a resident, such certificate to be obtained in the following named manner
>
> The applicant for a certificate of expert qualification shall furnish reliable evidence to the State Board of Medical Examiners that he is legally qualified to practice in this State (New York), is of good standing in the medical profession, and has not had less than five years experience in the practice of the special branch in which he desires to stand as an expert, and shall also pass a satisfactory examination in the branch or branches in which he is to become an expert
>
> On the passing of such examination to the satisfaction of said Board, there shall be issued to him, in the same manner as a license to practice is now issued, a certificate of qualification to give expert testimony in the particular branch therein specified, and when properly filed all physicians holding such certificates shall be eligible for appointment by the courts, or may be called by defence as expert witnesses
>
> The testimony of any medical witness called by either plaintiff or defendant, not holding such certificate shall be restricted to evidence of fact

My own opinion is that could such a qualification test be set up, it would practically settle the question of obtaining reliable expert testimony, and eliminate most of the objectionable features of the present system It would seem that such a qualification could be demanded by the State without the infringement of any constitutional feature of the law, or an abridgement in any sense of the rights of the citizen or practitioner

There could be no question, it seems to me, as to the right of the State insisting upon such a qualification, no more than in its insistance upon a certificate of qualification to practice general medicine One of the objections raised by some of the committee to this feature was that physicians would not qualify, this, I think is erroneous, for any duly qualified practitioner who cared to become an expert could not object to this method of examination It is to be hoped, however, that many who, under our present system, might pose as experts, would not qualify as such I believe that qualification is the first step in the right direction, and that other remedial legislation would quickly and naturally follow

Very respectfully, J B Ransom, M D

Congress of Leprologists

New York, Oct 14, 1896

To the Editor —I have sent the following to the American Public Health Association Will you kindly publish in your next number?

A Congress of Leprologists and delegates of all civilized governments will in all probability, be convened next year for the suppression and prevention of leprosy It was at first proposed to hold this congress at Bergen, Norway, out of compliment to Hansen As the latter has renounced his claim, and left that question to be decided by those who will work for the scheme, and as there is among the present workers a division of opinion as to the comparative merits of London and Moscow, nothing can be said for the present, as to the place where the congress will meet Invitations will be issued, we hope, by one government to the other governments, to send each an official delegate These delegates will form a permanent international committee, whose business it will be to formulate laws suitable for each country The question of the suppression and prevention of leprosy, is of paramount importance to Canada, Mexico and the United States Lord Aberdeen, President Diaz and President Cleveland have already been appealed to, the first through Dr Smith, Medical Superintendent of the Leper Asylum of Tracadie, and Inspector of Leprosy for Canada, the second through Dr Carmona Y Valle, the President of the Second Pan American Medical Congress to meet in the City of Mexico, next November, and President Cleveland, through the Secretary of State

There are in Canada three centers of leprosy, a Scotch, Irish and French one in Nova Scotia and New Brunswick, a Chinese center in British Columbia and a possible Norwegian one about Winnepeg, from communication with our States, the Dakotas and Minnesota

In the United States there is danger from the Chinese invasion on the Pacific coast, and from the Norwegian center above mentioned, but the greatest peril consists in the possible contamination of our southern negro race from the Louisiana and West Indian lepers, and possible contamination from the Hawaiian islands

Mexico is exposed to Chinese and Japanese invasion and, moreover, the harbors of Mazatlan and Acapulco may receive inoculation from the 27,000 lepers of Colombia, South America, through mercantile intercourse

Queen Victoria, by her private secretary, Sir Arthur Bigge, has expressed sympathy when informed of this project and the matter has been referred to her responsible advisers

As this memorial did not reach the Advisory Council of the American Public Health Association in time to be brought before the recent meeting at Buffalo, I take the liberty to bring the matter under the eyes of the Association in an open letter, urging that the influence of the Association, which is known to be great, be brought to bear upon the governments of Canada, Mexico and the United States, so that we may obtain from each of them a delegate to the proposed Congress

Very Respectfully, Albert S Ashmead, M D

PUBLIC HEALTH

Consumption Among the Colored Population —A writer in the *Medical and Surgical Reporter* for October presents the statistics of eight of the principal cities of the South which prove that the proportion of deaths from consumption among the colored races as compared with the total mortality, is more than 50 per cent greater than that of the white population, while the death rate per thousand from this disease is nearly three times as great

The Bubonic Plague —The *Lancet* states that an outbreak of fever, attended by some of the features of what is alleged to be bubonic plague, has taken place at Bombay and has been attended by many deaths The occurrence has naturally excited a good deal of alarm among the native population, many of whom have left the city The troops of the British and native armies have been temporarily prohibited from entering the affected locality, and the government has appointed a committee to inquire into and report upon the subject Mr Dutt has arrived at Calcutta with the special object of aiding the committee in their investigation The outbreak is probably of the same nature as that which occurred lately in China and Hong Kong The *British Medical Journal* adds We hope no time will be lost in inviting Dr Yersin to practice his serum injections for the cure of the plague His success with it has been reported in this Journal

Tetanus Antitoxin in Brooklyn —The Department of Health of Brooklyn, N Y, has issued under date of October 8, a circular regarding tetanus antitoxin, as follows

"The health department is now prepared to furnish to physicians and hospitals antitoxic serum for the treatment of tetanus Each vial will contain 20 c c of the serum, but the dose will vary with the age of the patient, the severity of the attack and the time in the disease when the treatment is begun The remedy is administered in the same way as diphtheria antitoxin, by hypodermic injection, using a large syringe and carefully sterilizing the syringe and the skin before making the injection Some point on the anterior surface of the body is preferable for the injection Too much emphasis can not be placed on the vital importance of injecting the serum at the earliest possible moment, as every hour's delay decreases the chances of success and requires larger doses to overcome the amount of toxin produced and absorbed When the treatment is begun at the first appearance of tetanic symptoms, 20 c c should be injected at once, and 10 c c at intervals of six hours for the four following days If the treatment is not begun until three or four days after the onset of tetanic symptoms, 20 c c should be used at once, and repeated at short intervals according to the results The use of the serum does not preclude the employment of other methods of treatment by the use of antispasmodics The wound should be treated with some strong preparation of iodin, such as strong tincture, to destroy the toxin in it Carbolic acid and bichlorid of mercury are of little use for this purpose The exact value of this method of treatment has not been fully determined, and it is very desirable that full reports be sent to the department of each case and the result of the treatment"

Baths for Miners —On the European continent mining companies have, of late years, devoted much attention to providing facilities for the miners to perform their ablutions and to change their wet and dirty clothes, so as to enable them to return home refreshed in dry and warm clothes A very elaborate lavatory has been erected at the Hibernia mine, Gelsenkirchen The plant comprises shower baths for 1,600 miners and private bathrooms for the managers and overseer The success that has attended the use of lavatories in Westphalia led to the erection of two admirable establishments at the Dudweiler and Kreuzgraeben collieries, in the Saar coal field At Dudweiler the massively built house, which is in direct communication with the mouth of the adit, has an internal area of 108 by 61 feet The height of the roof is 16 feet Two high double walls divide the building into three sections, two of which serve for the married miners and the other for the young unmarried ones Light is furnished by forty five windows and three skylights, and, at night, by three arc lamps The floor is of cement, with a slope of 1 in 40 There are fifty-five shower baths, each in a cell, five of these being supplied with cold water and the others with water heated in summer to 86 degrees F, and in winter to 95 degrees F Each cell measures 4 feet 6 inches by 3 feet 3 inches, and is used by two miners at the same time The cold water cells are somewhat smaller and are arranged for one person only In the dressing rooms there are a number of forms, and for each man's clothes there is a hook and line running over pulleys at the ceiling The clothes hung up at the ceiling dry very rapidly Each hook is marked with the man's lamp number The building is heated by steam pipes For a bath, seven gallons of water are required Of the 1,900 miners employed in the mine 1,200 bathe regularly Seven hundred miners, however, live in barracks where ample washing accommodation is provided The lavatories have been in existence at Dudweiler and Kreuzgraeben collieries since 1891, and have answered their purpose admirably —*Health*, October 3

Detention Hospital for Lepers at Honolulu —Assistant Surgeon Ammen Farenholt, U S N , writes to the *Boston Medical and Surgical Journal*, September 3, the following account of the above institution "In December last, while at the Hawaiian Islands, on the U S S *Baltimore*, I visited Kalihi, the hospital of detention for lepers, three miles north of Honolulu The primary object of this institution is to afford shelter for the patients condemned as lepers and awaiting transportation to the Island of Molokai, the government leper settlement, and also to serve as a home for the suspects, those in whom the symptoms of the disease are not sufficiently well marked to admit of a positive diagnosis There are also 30 little patients here, the children of the lepers at Molokai, 23 are graduated from the institution, that is, having passed six or seven years under observation, and showing no signs of disease, they were allowed to go into the common walks of life Only one of these has become a leper, and he lived subsequently with an infected family in Honolulu In about one third of the cases both the father and mother were lepers All inmates are carefully watched and made to remain in the quarters assigned to patients in the same condition as themselves The hospital consists of five or six one storied whitewashed houses, arranged around a square filled with palm trees and beautiful beds of flowers Sisters of Charity from Syracuse, N Y , have charge of the hospital Every month the suspects brought in by government spies are examined by a board of five physicians, also appointed by the government The patients appear in the examining room, and are inspected by each medical officer in turn, who writes his verdict opposite the number of each case on the list before him The examination being over, the recorder reads off the numbers, and the members in turn give their opinion, the words *leper*, *non leper* or *suspect* being used Three votes out of the five are necessary for a decision The first are held until a sufficient number are waiting, and then they are transferred to Molokai, the second are allowed to return to their homes, and the third are retained for further observation An examination of suspects was being held at the time of my visit, to which I was kindly invited by the senior physician Facial paralysis, however slight, absorption of joints and later of the bones themselves and a reddish or a whitish macular eruption, are the most common primary lesions, as the disease is seen in Hawaii The population of the islands is about 38,000 (native Hawaiian) At Molokai there are 1,100 lepers, and it is said that only one in every four is detected Thus out of a population of 38,000, 4,000 are lepers, almost 12 per cent

The Daily Medical Inpsection of Schools in a Great City —We think it is not generally known, even among those who are considered to be sanitary adepts, that Boston has, after years of effort, the benefit of a genuinely systematic school inspection The August number of the *Archives of Pediatrics* shows how this innovation was secured by the Board of Health as a consequence of a very severe epidemic of diphtheria The general plan of operations, that has now been in force for a year, and that was, as we believe, devised or matured by Dr S H Durgin, is the following The city was divided into fifty districts, giving an average of about four school houses and fourteen hundred pupils to each district No difficulty was experienced in finding well qualified and discreet physicians who would undertake the duties prescribed The Board appointed one physician for each district, with a salary of $200 a year, plus the honor and satisfaction of serving in a good cause His duty is to make a visit to each master's school daily soon after the beginning of the morning session The master receives from each of the teachers in his district, early reports as to the appearance of symptoms of illness in any pupil in their charge These reports are given to the visiting physician, who at once examines the reported children and makes a record of his diagnosis and action in books furnished for this purpose, and kept in the custody of the master If the visiting physician finds the child too ill to remain in school, he advises the teacher to send the child home for the observation and care of its parents and family physician If the illness is from a contagious disease, the child is ordered home and the case reported to the Board of Health The medical inspectors never undertake to give professional treatment in any case They merely point out the need of professional treatment where the need exists The treatment itself must be received from the family physician or in the hospitals or in the dispensaries Incidental to this school inspection the same corps of medical men is also serving as agents of the Board of Health in the control of contagious diseases which are treated at home The Board of Health sends to each of the school inspectors, every morning, a full list of the cases of diphtheria and scarlet fever which have been reported during the previous twenty four hours Each medical officer selects the cases reported in his district, visits them to see if they are properly isolated at home, leaves a card for the attending physician, politely informing him of the official visit and reports his approval or disapproval of the isolation at once to the Board of Health for its action If the patient is properly isolated, the officer places a card on the door of the room to indicate the official designation of such room for the isolation of the patient If the case is not properly isolated and such isolation can not be commanded at home, he reports such facts to the Board of Health, and such patient is at once ordered to the hospital He makes another visit to the patient This school inspector and agent of the Board of Health is indirectly held responsible for the proper isolation of the patient at home, for causing the patient's removal to the hospital when necessary, and for the patient's release from isolation, in other words, the Board of Health is thus provided with trustworthy information upon which it can act for the best protection of the schools and the public against the spread of contagious diseases

NECROLOGY

A B Shaw, M D , St Louis, aged 49 years Dr Shaw died a martyr to duty Infected in the performance of duty years ago, his knowledge of the clinical course of that infection and its dreadful possibilities placed him often in a frame of mind to which the physical suffering which it entailed bore no proportion, and only those who were made the confidents of his mental agony can faintly realize what suffering there was for years hidden under the pleasant exterior of an apparently healthy body

Sir George Murray Humphry, aged 76 "Humphrey of Cambridge," one of the greatest medical figures of our time, revered and loved by generations of medical men and honored by individuals and scientific associations at home and abroad The new School of Medicine at Cambridge is his most lasting monument The *Lancet* mentions that he treated cases of tetanus by giving nourishment in all possible ways and tobacco smoking to excess Good port wine was his favorite internal remedy This treatment always soothed the patient, and the writer has seen three cases recover under it He commonly took his holidays abroad, and visited continental hospitals and museums, seldom failing ts bring back safely packed in a portmanteau some fragments of humanity which would enrich the Cambridge collection Indeed, he looked upon the museum as only second to the hospital in importance He often said that he turned every moment of his life to some account Even his severe illnesses were not without their utility, for his dangerous attacks of phlebitis furnished medical literature with one of the best monographs on the subject of venous thrombosis which has ever been written One of his aphorisms to his pupils was "Eyes first, fingers next, ears last"

SOCIETY NEWS

Second International Congress of Charities and the Protection of Children —Nine governments were officially represented at the Congress United States, Switzerland, France, Hungary, Portugal, Sweden, Spain, Luxemburg, and the Argentine Republic The resolutions adopted evidence the modern tendency to a more rational conception of the preponderant importance to the State of the correct physical and moral development of the child, and the responsibility of the community to the children of the poor and degraded They endorsed the formation of societies to supply medical care and assistance to mothers before and during confinement, with rest for four weeks afterward, and advice and assistance for mother and infant during the entire nursing period, in charge of local committees in every district with over twenty five infants to be thus protected, crèches near industrial establishments, under strict daily medical supervision, with guarding classes for children after school hours until the parents return from work, more judicious education of the young especially in morality, in view of the increasing juvenile criminality evidenced by statistics produced, complete separation of the young from adult criminals, and closer organization of all charities according to English and American methods The Congress also voted that the expense of assistance to foreigners should be reimbursed to the community by the State, and that the indigent should in every case be returned to their home by birth or naturalization

PRACTICAL NOTES

Pernicious Anemia Cured with Bone Marrow —A young soldier was brought to the hospital in pernicious anemia consecutive to an attack of dysentery He was so feeble that he could not rise, there was malleolar edema, ascites and dilatation of the right heart with systolic murmur at the apex Iron and arsenic produced no effect Blumenau cured him in two months and a half with the entire disappearance of the complications by giving him 90 grams a day of raw bone marrow, spread on bread or taken in soup, with no other medication —*Semaine Méd*, September 23

Sulphur Baths in Whooping Cough —Among the many treatments recommended for this disease, the *Journal de Méd de Paris*, September 20, describes Josset's prolonged baths, with 0 75 gr sulphureted potassa to the liter, the temperature at 97 degrees, and the duration of the bath from twenty five to forty five minutes, according to age, once a day, the head alone exposed above the water With this treatment all complications were avoided, the sulphur evidently acting on the special whooping cough bacillus, with a beneficial antiphlogistic effect on the bronchial mucosa and a revulsive action on the skin It is rarely necessary to administer more than fifteen baths as the cure is usually obtained long before this

Cause of Inefficacy of Sublimate Spray as a Disinfectant —Chavigny has found that the sublimate simply affects the outer surface of the microbes, producing a superficial layer of coagulated protoplasm, which temporarily destroys their virulence but readily washes off, when they recover all their former virulence Hydrosulphate of ammonia is one of the substances that promptly restores them to their previous activity Among other experiments, thin layers of tuberculous sputa exposed for a long while to direct sublimate spray, produced fatal tuberculosis every time when rabbits were inoculated with them —*Annales de l'Institut Pasteur*, June

Painless Treatment of Ophthalmia Neonatorum —Hjort of Christiana states that the same results obtained with the classic treatment of this affection can be secured with much less trouble and inconvenience, by first dropping in oxygenated water at 1 or 1 5 per cent, which causes the pus to effervesce. The eye is then washed out with 2 per cent boricated water, working the lids slightly until the pus has all been cleaned out, when the solution of nitrate of silver at 1 per cent is gradually instilled This method does not require the reverting of the eyelids, but it should be repeated four times a day at first. It can be safely intrusted to a well trained uurse —*Semaine Médicale*, September 23

On the Misuse of the Pessaries —Dr A J C Skene *Brooklyn Medical Journal*, September, participated in a discussion of Dr John Byrne's paper on the needs of minor gynecology, before the Gynecological Society of the city above named He generally confirmed the opinion of Dr Byrne that the misuse of pessaries, in the treatment of uterine retroversion, was every day tending to produce conditions, remediable in themselves, that are absolutely incurable, that too many of these implements as sold in the instrument makers' stores were viciously devised to produce an atrophy of the tissues impinged upon and thereby converting simple retro displacements into incurable flexions Dr Skene's remarks were in part as follows: "With reference to the use of the pessaries, and that is only one thing in which we are apt to go astray in minor gynecology, I have certainly had some experience, though limited no doubt, compared to that of Dr Byrne There was a time when I introduced very many pessaries, but now I think I divide my time about evenly between removing those that have been introduced and using others that give relief It is an unfortunate thing that very few have had practice and patience enough to master the mechanisms of displacements and the mechanic appliances for their relief I have no doubt there are hundreds of men who do laparotomy and all surgical operations in the domain of gynecology who could not fit a pessary to correct a displacement any more than they could make boots to fit themselves"

Tubercular Meningitis Ending in Recovery —Dr Jenssen in the *Deutsche medicinische Wochenschrift* reports a case of the above description The writer adverts to the rarity of recovery in this disease In a few cases the diagnosis has been established by finding evidence of a past tuberculous meningitis, the patient having died of some other cause In Freyhan's case of recovery, tubercle bacilli were found in the fluid drawn off by spinal puncture The author then records the following case A man, aged 19, was admitted in May, 1892, with headache, stupor, vomiting and constipation The temperature was raised and at one time the pulse only numbered forty-two per minute Later there was ocular paralysis and retraction of the head Some fourteen days after admission the patient began to improve and he was discharged well a month afterward Three years later he was again admitted into the hospital with early phthisis The disease ran a rapid course and he died four months later At the necropsy a yellow mass, composed of minute tubercles, and measuring four centimeters long and two centimeters wide, was found running along each side of the longitudinal fissure The pia mater was of a milk white color in several places over the convexity of the brain, there minute tubercles were also seen The first named tubercles consisted of detritus, fat and a few cells, but no fibrous tissue, and the last named of fibrous tissue and a few cells. In no instance were tubercle bacilli found At the base of the brain the same white spots containing tubercles were seen about the chiasma and Sylvanian fissures In these white areas the pia mater and arachnoid were adherent to the underlying brain tissue As regard the treatment of this attack of tuberculous meningitis, the head was shaved and iodid of potassium was given in large doses, 8 g were at first administered in the day, but this quantity was rapidly increased The patient took as much as 950 g during the illness There was a slight coryza, but no other unpleasant symptom All the secretions and excretions gave a marked iodin reaction The author thinks that the iodid had undoubtedly a favorable effect on the disease This treatment is not new, but these large doses of iodid have not within the author's knowledge been used before

New Operation for Luxation of the Tendons —Luxation of the tendons does not occur frequently, but is a source of great annoyance when it does happen An article in the *Revue de Chirurgie* for September reviews the cases on record and the various methods of treatment, concluding with a new operation performed by Kousmine of Kazan The patient had dislocated the tendons in an accidental fall two years previously, when his foot had slipped out to one side Bandaging had proved ineffectual, and in spite of every precaution in stepping, the peroneal tendons sprung out of their normal position, especially in supination and flexion, producing great pain and causing the foot to slip, until walking was practically impossible A half moon incision was made to the bone behind and below the external malleolus, and a trapeze shaped space on the periosteum cut around, the base of the trapeze corresponding to the lower edge of the malleolus, after which the enclosed small, flat piece of bone was cut out with the scissors and raised perpendicularly to the malleolus A couple of nickel nails were inserted to hold this little piece of bone up like a trap door, and keep the tendons in place A plaster cast was then applied The pain was trifling and soon passed away There was no fever In seventeen days the cast was changed, the nails withdrawn, and the tendons found in their normal position, with a considerable elevation thrown up on the outside of the malleolus. Another plaster cast was applied and the patient left the hospital with advice as to slight massage and exercise after removing the cast in twenty eight days The results of the operation have proved curative and brilliant The patient is entirely relieved of his functional troubles The neoformation of the bone answers its purpose perfectly, while the traumatism was insignificant in the simple operation, as neither the tendons nor the aponeuroses were wounded

MISCELLANY

Ammonia in Alcoholism —Dr Baratier recommends, in *El Siglo Medico*, the addition of ammonia to wine or liquor in order to produce a distaste for alcoholic beverages After a few doses the disgust to the mixture becomes so intense that even the sight or smell of wine is unpleasant —*St Louis Med Journal*, October

The Significance of the Diazo Reaction in Phthisis —Beck, from investigations carried out in the Institute for Infectious Diseases at Berlin, has come to the conclusion that the appearance of the diazo reaction in the urine of patients suffering from phthisis makes the prognosis unfavorable, while its long continuance forebodes an early death —*Boston Med and Surg Journal*

Bahia's Participation in the Pan American Medical Congress not Possible —The *Gazetta Medica da Bahia*, Brazil, states that the profession at Bahia does not expect to take any part in the Pan American Congress, either personally or by scientific contributions The circulars in regard to the Congress have only just been received at Bahia, but this delay is not the cause of the abstention, but the fact that the same date has been appointed for the first medico surgical congress to meet in that city

Trained Nurses in California —The *Medical Record* states that many trained nurses from Philadelphia and Baltimore have recently been induced to go out to San Diego and other places in Southern California on the representation that they could find employment there that would pay them $20 to $25 a week On arriving there, however, they have found that there was no work for them, and that, even if there were, they could not obtain any such remuneration for their services, and they have in many cases had to send to their friends in the East for money to enable them to return home

Provision for Baltimore Indigent Lying in Women —Recognizing as is stated, that the Maryland Lying in Hospital, of Baltimore, a body corporate, is well and firmly established in said city, and particularly well equipped for the treatment of lying in women, and that it is desirable that the benefits and advantages of such hospital should be extended to the indigent lying in women of the State of Maryland, so that skilled and humane treatment be afforded them, the General Assembly of the State enacted, in chapter 148 of the Laws of 1896, that the sum of three thousand per annum be appropriated for each of the years 1896 and 1897 for the maintenance of free treatment for indigent lying in women in said hospital

Chairs for Maryland Salesladies —A Maryland statute of 1896 provides that all proprietors or owners of any retail, jobbing or wholesale dry goods store, notions, millinery or any other business where any female help are employed for the purpose of serving the public in the capacity of clerks or salesladies, shall provide a chair or stool for each one of such female help or clerks, in order that during such period as they are not actively engaged in making sales or taking stock they may have an opportunity to rest The penalty for the first offense is a fine of from $10 to $100, and in the event the owner or proprietor shall continue to disobey, he shall be subjected to a fine at the rate of one dollar a day, daily, for every chair he fails to furnish his said employes

Alvarenga Prize of the College of Physicians of Philadelphia —The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Senor Alvarenga, and amounting to about $180, will be made on July 14, 1897, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered Essays intended for competition may be upon any subject in medicine, but can not have been published, and must be received by the secretary of the college on or before May 1, 1897 Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author It is a condition of competition that the successful essay or a copy of it shall remain in possession of the College other essays will be returned upon application within three months after the award The Alvarenga Prize for 1896 was not awarded THOMAS R NEILSON, Secretary

Illinois State Conference of Charities and Corrections —It has been found necessary to change the date of the proposed State Conference of Charities and Corrections The conference will take place on Thursday and Friday, Nov 12 and 13, 1896, at the Capitol in Springfield, and not **November** 18 and 19, as pre viously announced Among those who it is hoped will take part in the program are H H Hart, secretary Minnesota State Board of Charities Ernest Bicknell, secretary Indiana State Board of Charities, Bishop Spalding, Dr Julia Holmes Smith, Miss Jane Addams, Judge Carter of Chicago and others Complete program will be published later Classes for the State Schools for Blind and for the Deaf and Dumb will give exhibitions Governor and Mrs Altgeld will receive the Conference at the Executive Mansion Excursion rates of a fare and a third will be made by the railroads, and special rates will be obtained at the hotels and boarding houses in Springfield For any information or services desired, please address Geo F Miner, Secretary State Board of Charities, Springfield

Cause and Prevention of Glaucoma —The etiology of glaucoma is still disputed, but Schoen of Leipsic, the new professor of ophthalmology, asserts in an article in the *Wien klin Rundsch* , Nos 26 to 31, that no one need lose his sight from this cause, unless he chooses It can always be prevented if the eyes are seen in time by an expert and his warnings heeded, as the invariable cause is excessive strain in the effort of accommodation As the number of the efforts increase with age, the strain increases and glaucoma is the result The particulars of the last 140 cases he has treated are 48 per cent hypermetropic, not one had possessed a distance lens Astigmatism was present in 33 per cent, in none had the astigmatism been corrected In 20 per cent there were no glasses, or they had been utterly inadequate Nearly twice as many cases of glaucoma occur among women as in men, the former shrinking from wearing glasses until too late What may be a trifling effort for the eyes at first, becomes in the course of years an exhausting strain, and while this strain of over exertion in the efforts of accommodation produces anatomic changes which lead directly to glaucoma in time, yet any constitutional morbid tendency, any weakening or depressing cause, violent coughing, night watching, etc , may hasten its appearance

New Dental Law for Maryland —Chapter 378 of the Maryland laws of 1896, which was approved April 4, 1896, repeals Article 32 of the Code of Public General Laws, entitled "Dentistry," and reenacts the article with many changes in it The new law makes it unlawful for any person to practice dentistry in the State unless he shall have obtained a certificate therefor It then provides that there shall be a State board of dental examiners, which shall consist of six practicing dentists of recognized ability and honor, who have held regular dental diplomas for five years They are to be appointed by the governor out of a list proposed by the Maryland State Dental Association Six years is the regular term of office Any member who shall be absent from two successive regular board meetings shall cease to be a member of it The regular meetings are to be held in May and November of every year, with special meetings as required Any person 21 years of age, who has graduated at and holds a diploma from a university or college authorized to grant diplomas in dental surgery by the laws of any one of the United States, may be examined by said board with reference to qualifications, and upon passing an examination satisfactory to said board, his or her name, residence or place of business shall be registered and a certificate shall be issued to such person Any graduate of a regular college of dentistry may, at the discretion of the examining board, be registered without being subjected to an examination A temporary certificate for a specified time may be issued by the officers of the board to any applicant holding a regular dental diploma duly registered by a board of dental examiners created by the laws of any one of the United States, but no such certificate shall be issued for any longer time than until the next regular meeting of the board The fee for this temporary certificate shall be $5 Transcripts from the book of registration, certified by the officer who has the same in keeping, with the seal of the board, shall be evidence in any court of the State Every person shall be said to be practicing dentistry, within the meaning of this act, who shall for a fee, salary or other compensation, paid either to himself or to some one else for services rendered, perform operations or parts of operations of any kind pertaining to the mouth, treat diseases or lesions of the human teeth or jaws, or correct malpositions thereof The penalty for a violation of these provisions is a fine of not less than $50 nor more than $300, or confinement in jail not more than six months But nothing in this article shall be so construed as to interfere with the rights and privileges of resident physicians and surgeons or with persons holding certificates duly issued to them prior to the passage of this act, and dental students operating under the immediate supervisions of their instructors in dental infirmaries or dental schools chartered by the general assembly of Maryland Money received for examination and registration, the fee therefor being $10, shall be used toward paying the expenses of the board All fines received are to be paid into the common school fund of the city or county in which conviction takes place

Recent Additions to the Army Medical Museum —One of our military papers, the *Army and Navy Journal*, in its issue of October 17, has an article entitled "New Surgical Appliances," which gives the results of an investigation into the additions made to the Army Medical Museum during the past year and particularly with regard to those that relate to the transportation of wounded The article displays an excellent knowledge of the subject It is as follows

> The last Congress appropriated $5 000 for use of the Army Medical Museum, at Washington A portion of this sum has been expended in the purchase of field appliances used by foreign countries for exhibition in the museum side by side with the improved equipments of the hospital corps of the United States Army Many of the new foreign acquisitions have been received and a place has been found for their permanent display The countries thus far represented are Prussia, Switzerland, England, France, Austria Hungary, Norway, Spain and Japan, and the collection includes litters on wheels and for hand bearers, knapsacks, surgical pouches, chests and instruments, and articles for the use of the sanitary and culinary departments of the hospital corps The litters and general appliances of the European armies, excepting possibly England, are characterized by exceeding bulkiness and weight, though admirable in many other respects The Prussian and Spanish mattresses, in particular, are remarkable for comfort and hygienic qualities The Norwegian litter is an unwieldy affair, and is very uncomfortable The Japanese have a light and easy bamboo bed on wheels, with carriage top, resembling the jinriksha, which has only one undesirable quality—its fragility, the bamboo offering little resistance to great weight and shocks The Japanese leather bound medical chests and French pouches and panniers are admirable for completeness of outfit and economy of space Some tiny surgical pouches of the Austrian army are marvels in this respect Other notable articles are a Spanish seat for carrying wounded men, and the English and French litter carriages and beds
>
> The recent additions to the collection of articles used in the United States service are important and compare favorably with the best similar appliances in use abroad Our new litter is much lighter than any other, except the Japanese, is much more durable than that, and in every respect is considered admirably adapted to the use of our arms The new regulation adjustable sling, which remains on the bearers, is a great improvement over the old method of bearing the litter, both as regards the comfort of the wounded person and of the bearers The Quartermaster's Department has adopted this litter and each company is to receive two litters The new drill regulations for the Hospital Corps, recently issued, incorporates a revision of the manual of the litter adapted to the new improvements Some other changes have been made in the regulations such as the abolition of side arms for Hospital Corps men, and changes in the manner of packing and transporting clothing The new operating table for field hospital work, which finds a place in the collection, seems as nearly perfect as science and skill can make it The latest improvement is an arrangement of cranks by which a patient may be lifted or lowered, or his position changed without the interposition of the attendant's hands

Of late acquisitions the telephonic bullet probe and forceps, made by Tiemann & Co , New York, is a curious mechanism and would be of greater value if the practice of probing were more generally pursued The instrument consists of a band of metal to be placed around the head of the surgeon, a bell being affixed near the ear From the bell extends a wire connecting with the probe, both being in communication with an electric battery The principle is that the bell shall ring when the probe strikes the bullet It is customary now, however, and has been for some years, to allow gunshot wounds to heal with out suppuration, and the probe is not employed unless the ball is pressing upon some vital center, or there appear symptoms of poisoning If a wound be made by new and clean ammunition there is little or no danger of poisoning If a cartridge has been carried about a long time in the pocket or other exposed place, it is apt to accumulate foreign matter of a deleterious nature

Other recent additions to the museum are some English water filters and sterilizers, a litter with disjointing parts and detachable slings, adopted by the Massachusetts Volunteer Militia, and cabinet field desks of the United States Army, which may be folded in the form of chests for transportation

Souvenir Volume of the Centennial of the Faculte de Medecine — This large quarto and the accompanying atlas of 130 portraits is a historical sketch of the institution and what it has accomplished, compiled by a special committee and published at the expense of several of the medical publishers of Paris It is a "publication de grand luxe," as evidenced by the price, 100 francs, or about $20

Hospitals

Typographical Union Hospital —At the sixth day of the convention of the International Typographical Union the subject of providing for the erection of a hospital in connection with the Childs Drexel Home for Old Printers, which is located in Colorada Springs, came up for discussion Fifteen thousand dollars was provided by the International Union for the building of the hospital, which amount is to be contributed by the printers all over the land as a popular subscription The amount is expected to be raised by Christmas ——The soliciting committee of the Augusta, Me , city hospital has reported subscriptions to the amount of $5 500 This amount assures the purchase of a hospital site this fall ——The annual meeting of the Board of Directors of the Kensington Hospital, Philadelphia, for Women was held October 12 During the last year 287 patients have been treated in the wards, and 274 in the dispensary, making an increase of 127 over the previous year Four hundred and sixty two operations have been performed and the cost of maintenance for the year was $10,723 An appeal is made for additional funds to erect a new building and also to provide for the care of an additional number of free patients ——The new building erected as an annex to the Flower Hospital of New York was opened for the reception of patients October 2 ——The corner stone of the St John's new hospital at Long Island City, L I , will be laid November 1 ——The executors of the estate of the late Very Rev Fr McCabe, who was pastor of St Charles church, and vicar general of the Providence diocese, who died several years ago, have intimated that $500 will be shortly forthcoming from this estate with which to establish a free bed in the Woonsocket, R I , hospital This is in fulfillment of the intention of the deceased rector

Washington

Located by the X Rays —Dr John Van Renssalaer of the surgical staff of the Garfield Hospital successfully located a bullet by the X rays and removed it on the 8th inst The bullet was located deep and posterior to the hip joint and had made the woman practically an invalid

First Medical Examination for Practice in the District —The first examination of physicians for license under the new medical law, was held on the 8th to 11th inst , in the rooms of the Civil Service Commission The first three days were devoted to written, and the last day to oral examination

Changes at the Garfield Hospital —Dr A L Stavely, who has been the surgeon in chief and superintendent of Garfield Hospital for three years past, severed his official connection with that institution on the 1st inst , in order to resume private practice Dr Stavely tendered his resignation several weeks ago, and it was accepted in a very complimentary letter from the board of directors Dr Stavely for three years was assistant to Dr Howard Kelly of Johns Hopkins Hospital, Baltimore Dr M D'Arcy Magee will act temporarily at Garfield Hospital in place of Dr Stavely, while Dr J Milton Heller is to serve as senior resident physician

Changes at the Central Dispensary and Emergency Hospital —The following is the medical staff of the hospital and the medical assignments for the ensuing year Health Officer, Dr W C Woodward, Sanitary Officer, John A Frank Consulting staff Drs N S Lincoln, J Ford Thompson, W W Johnston, J Taber Johnson and G L Magruder Diseases and injuries of the eye and ear Dr Swan M Burnett Diseases and injuries of the throat and chest Dr T Morris Murray Diseases and injuries of children and orthopedics Dr William H Hawkes Diseases peculiar to women and acute venereal of women Dr H L E Johnson Surgical diseases Dr James Kerr General diseases, skin diseases, and venereal of men Dr G B Harrison Mental and nervous diseases Dr E L Tompkins The emergency department has been placed back in its original position under the executive officer, with assistants in Drs W P Carr, A A Snyder and John Van Rensselaer A total of $15,000 is asked for by the hospital authorities to run the hospital next year, and the suggestion made last year as a means of liquidating their present indebtedness is repeated The indebtedness of the hospital is $20,000, on which an annual interest is paid A total of 10,433 new cases were treated in the dispensary during the year, and in the same period 2,828 new cases were cared for in the emergency department, with 1,925 redressings The number received into the wards of the hospital for treatment and care was 189 , deaths 49 , autopsies 28 , ambulance calls, 421 , surgical operations 1,443

Applicants for Police Surgeon —Twenty five young medical men recently took the examination for the position of Police Surgeon President Kleinschmidt, of the Board of Medical Supervisors, conducted the examination

Entitled to Licenses —Physicians who were registered at the health office at the time of the passage of the recently enacted medical practice act are entitled to licenses upon application to the board of medical supervisors Blank forms for application can be obtained at the health office upon request in person or by letter

Medical Association Elects New Members —At the stated meeting of the Medical Association, recently held, the following new members were elected to active membership Drs Chas L Allen, Hugh C Duffey, Robt H Graham, E M Hasbrouck, H Warfield Howell, G T Howland, Francis Leiben, R F Mason, Jr , W L Masterson, E D Perkins, C V Petteys, F M Phillips, M S Patten, A M Ray, E M Schaeffer and Elmer Satheron

Medical Society Elects New Members —At the recent meeting of the society the following new members were elected Drs Walter A Wells, Edwin Gladmon, John H Metzerott, Abbie C Tyler, Phoebe R Norris, Thomas B Crittenden, W R Maddox, Susan J Squire, A L Stavely, Walter D Cannon, Adeline E Portman, W A Caldwell At the regular weekly meeting of the society, held on the 14th inst , Dr J C McGuire read a paper entitled "Electrolysis in the Treatment of Diseases of the Skin," and Dr L Eliot read a paper on the subject of ' Suture Clamp Operation for Hemorrhoids "

Washington Obstetrical and Gynecological Society — The [illegible] meeting of the society [illegible] 16th inst and [illegible] by the [illegible] was the [illegible] d committees for the ensuing year, and resulted in the re election of all the former officers President, Dr G B Harrison, Vice presidents, Drs S S Adams and G N Acker, Treasurer, Dr John Van Renssalaer, Recording Secretary, Dr G W Cook, Corresponding Secretary, W S Bowen

Auxiliary Committee on Transportation for the Second Pan American Medical Congress —The International Executive Committee has appointed the following physicians as an auxiliary committee on transportation for the Congress Drs J B Murphy, Chicago, Robt Sattler, Cincinnati, A Walter Smith, Herkimer, N Y , J B Roberts and W B Atkinson, Philadelphia, A W Calhoun, Atlanta, Ga , H C Eccles, Charlotte, N C , I N Love, St Louis, Mo , Herman Mynter, Buffalo, N Y , Robt T Morris, New York City, R Matas, New Orleans, La , S Eliot, Washington, D C , Hugh Taylor and G Ben Johnston, Richmond, Va , A Morse, Elsora, Iowa, Walter H White, Boston, Hugh Hamilton, Harrisburg and Bedford Brown, Alexandria, Va

Pan American Medical Congress Transportation Arrangements —Dr H L E Johnson, to whom the arrangements for transportation were assigned by the International Executive Committee, has made his report which is now printing and will be circulated among the profession during the week He has arranged for one fare rate throughout Mexico and the United States except in the New England States and portions of Eastern territory By single trip from New York city to Mexico and return direct the entire cost will be Fare, $78 50, Pullman births round trip, $46, meals round trip, $32, total cost, $156 50 Living in Mexico $2 50 per day extra, intermediate points at proportional rates A special train has been arranged for through the American Tourist Association with Wm Campbell, manager, to leave Cincinnati on Tuesday, November 10, 9 A M , via St Louis and Eagle Pass, and make a twenty one day tour from there through Mexico and return for $189, from Chicago and return, $190, from St Louis and return, $183 55 This will include railroad fares, double births, meals in cars and hotels in Mexico and carriage hire and streetcar ride, steamer on Panuco River from Tampico and all necessary expenses of the trip The Baltimore and Ohio scenic route has been selected to carry the delegates from the North and East to meet the special train at Cincinnati, 300 persons have already signified their intention to make the trip An ocean route from New York by Ward lines has been arranged for, the total cost of which will be, including meals and stateroom, $78 Ten days required each way to make this trip The individual trip by rail will take six days each way

Tribute to Dr Toner —The annual report of the Government Hospital for the Insane, makes the following allusion to the late Dr Toner, President of the Board of Visitors, and includes the resolutions adopted at the time of his death "It is gratifying to us to know of such good work done in the Toner building How he who gave his name to that building would have rejoiced in it all, and yet the name comes to us now only to remind us of our loss Dr Joseph M Toner has been taken from us He had been so long an active member of the board, for so many years its president, that something seems wanting from this annual report without his genial presence and wise counsel in its preparation There was nothing about St Elizabeth or its inmates in which he did not feel a lively interest, and as the years went on, with his name on our hospital buildings and his pleasant face looking in so often upon us, to name Dr Toner was to suggest St Elizabeth It leaves a void that will not soon be filled He died suddenly at Cresson, where he had gone for a brief summer rest He had gone in the full expectation of returning long before our annual meeting, and looking forward to it as to a coming home He has found the home that his life had so well deserved, and contemplating the nobility of that life we find an inspiration to go on with the work here which lay so near to his heart "

Dental Inspectors for Schools —We notice in the *Medical Mirror* that the Ontario Board of Health recently adopted the following resolution "That dental inspectors be appointed by local boards of school trustees to periodically visit schools and examine children's teeth, and that a dental hospital be started in Toronto for the benefit of poor children, and these recommendations be urged upon the attention of the Minister of Education "

THE PUBLIC SERVICES

Army Changes Official List of changes in the stations and duties of officers serving in the Medical Department, U S Army, from Oct 2 to Oct 16 1896

Major Henry McElderry, Surgeon, is relieved from duty at Ft Robinson Neb , on expiration of his present leave of absence and is ordered to Ft Leavenworth, Kan , for duty at that station, to relieve Major Calvin DeWitt Surgeon U S A

Capt William P Kendall, Asst Surgeon U S A is relieved from duty at Ft Sam Houston, Texas and ordered to Ft Brown Texas for duty at that post to relieve Major Peter J A Cleary Surgeon U S A

Major Calvin DeWitt Surgeon, upon being relieved from duty at Ft Leavenworth Kan is ordered to Ft Monroe Va for duty at that station to relieve Major Edward B Moseley, Surgeon U S A

Capt Benjamin Munday, Asst Surgeon, will in addition to his present duties at Ft Wayne, Mich , examine recruits enlisted at Detroit, Mich and will furnish medical attendance at the recruiting station in that city

Capt William B Davis, Asst Surgeon, now Major and Surgeon, will be relieved from duty as attending surgeon and examiner of recruits in New York city, upon the expiration of the leave of absence granted him in S O 23 A G O Sept 30, 1896 instead of the conclusion of his examination for promotion as heretofore ordered by Par 4 S O 44 A G O Sept 4 1896 By direction of the Secretary of War

First Lieut George D DeShon, Asst Surgeon is granted leave of absence for four months to take effect after he shall have reported for duty at Washington Bks , D C

Col Charles H Alden, Asst Surgeon General and Major Calvin De Witt, Surgeon are detailed as delegates to represent the Medical Department of the Army at the Second Pan American Medical Congress to be held in the City of Mexico, Nov 16 to 19 1896 By direction of the Secretary of War

Capt N S Jarvis Asst Surgeon U S A , granted six months' leave of absence with permission to go beyond sea

Capt Jefferson D Poindexter Asst Surgeon will be relieved from duty at Ft Riley, Kan and will report in person to the commanding officer, Willets Point, N Y , for duty at that post

Major Peter J A Cleary Surgeon upon being relieved from duty at Ft Brown, Texas by Capt Kendall Asst Surgeon, will report in person to the commanding General, Dept of Texas, for duty as chief surgeon of that Department

PROMOTIONS

Lieut Col C R Greenleaf, Deputy Surgeon General, to be Asst Surgeon General, with rank of Colonel, Oct 10 1896, vice Town retired

Major William H Gardner Surgeon, to be Deputy Surgeon General with rank of Lieut Colonel, vice Greenleaf promoted, to date Oct 10 1896

Capt William W Gray, Asst Surgeon, to be Surgeon, with rank of Major Oct 10 1896, vice Gardner, promoted

Capt William B Davis Asst Surgeon, to be Surgeon with the rank of Major, Aug 11, 1896, vice Worthington, deceased

RETIREMENT

Col Francis L Town, Asst Surgeon General is at his own request having served over thirty years, retired from active service this date, Oct 10, 1896

Change of Address

Blech, Gustav, from Detroit, Mich to 728 17th St N W , Washington, D C
Davis Geo E from Salviso to Lawrenceburg Ky
Hamilton, John B , from Rand McNally Building to 100 State St Chicago Ill
De Hart, J N , from Round Lake to 137 Keap St , Brooklyn N Y
Goelet A H from 350 W 57th-St to 108 W 73d St , New York N Y
Gottschalk F B from cor Clark St and Chicago Av to 2030 N Halsted St Chicago, Ill
Hall Lemuel T , from 910 Vandeventer Av to 4240 West Belle Place, St Louis, Mo
Isbester R T , from Chicago, Ill to Salem, Iowa
King, Chas Lee, from Lamanda Park to Pasadena, Cal

American Medical Association

Vol XXVII CHICAGO, ILL , OCTOBER 31, 1896 No 18

ORIGINAL ARTICLES

ON THE TREATMENT OF FRACTURED SHAFTS OF BONE IN CHILDREN, SIMPLE, COMPLICATED AND COMPOUND

Read in the Section on Diseases of Children at the Forty seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga May 5-8 1896

BY THOMAS H MANLEY, M D
PROFESSOR OF SURGERY, NEW YORK CLINICAL SCHOOL OF MEDICINE NEW YORK

Fracture is, perhaps, the most common type of severe trauma incident to childhood, especially in the male sex

When the shafts of bones are involved, although union is more rapid than in the adult and repair is more complete, there are several special features of treatment of them, to be observed in the youth, if we would avoid possible dangers to the integrity of the damaged limb and secure the fullest degree of strength and function in it after recovery

Anatomic Considerations —It should be always remembered, that the bones of a child are immature structures, neither the epiphyses nor the apophyses have yet fused with the shaft by osseous union, through the absence of full calcification, the bone possesses unusual resiliency and elasticity Vascular and cartilaginous elements predominate in the osseous structures in infancy, both progressively diminishing as age advances The cancellous heads are the centers of great vascularity, the periosteum thick and is everywhere ramified by vessels which course through it and penetrate the cortex through Howship's lacunæ The medullary elements share in the activity of the nutritive forces, as is demonstrated by the bright crimson color of the bone marrow and its great proneness to bleed freely, when lacerated Nutrition and growth of the bone shafts at this epoch of life are maintained, by *periosteal* and *endosteal* sources, *i e*, from the circumference and ends Layer after layer of the myeloplaxes bud from the true bone roots, the cancellous heads, and are deposited in consecutive layers, on either end, preliminary to fusion and the formation of Haversian systems, while simultaneously from the circumference, the osteo-blastic layer of periosteum is steadily superadding concentric lamellæ, of neoblastic bone corpuscles

The overlying soft parts are in a high state of nutritive activity, neither the effect of time, nor occupation, nor the degenerative consequences of various local or constitutional disease have made their impress on the structures of the limbs, arterial sclerosis, venous varix, or territorial obliteration of the capillaries have not yet appeared

Although, in the young, growing limb the sanguinous supply is abundant, it is important to note that the volume of force of the blood-current in the great blood-trunks is not as great as in the adult, and accordingly in a corresponding degree, it is unable to resist the effects of pressure or tension

Etiology of Fracture in Childhood and Youth —Traumatic disorganization of bone in children more often results from direct, than indirect force, from the latter, we will more often find, epiphyseal separation or dislocation resulting Colles' or Pott's fracture in them, is rarely, if ever, witnessed

It has seemed that the shock attending the average simple fracture of a limb, was less in children than in adults Muscular action as a conservative factor, plays an unimportant *role* in these fractures As a rule force must be directly applied, or at all events in close proximity to where the bone sunders This will explain why we so rarely see the shafts or apophyses shattered, after sudden tortion or twists contiguous to a joint

I am not familiar with any constitutional disease in a child which predisposes to fracture There is no doubt, but in the cachectic, rickety, syphilitic, or badly fed the bones are more vulnerable and prone to give way to violence, but then, the effects of malnutrition are widespread, involving equally the soft parts and organs, as well as the osseous structures

It can not be said, therefore, that as a rule, there are any predisposing causes of fracture during the stage of growth and development, in this respect these fractures being widely at variance with the etiology of the same lesion in the adult That there is a strongly marked predisposition to fracture in some adult individuals no one can deny who has treated a large number of fractured shafts, but in my own experience with this traumatism in the child, I have never been able to find evidence to support the probability of predisposition

It seems, however, that with those who have had a large experience in the treatment of broken bones in modern children's hospitals, a belief prevails, that there are dyscrasia tending to fracture in the young Thus, Power speaks of osteopsathyrosis, or fragilitas ossium, rickets and even an inherited tendency, leading to fracture in young children (Surgical Diseases of Children, D Power, p 160) It is well to remember in this connection, that most hospitals for children are filled with unhappy waifs, illegitimate offspring and poor poverty-stricken orphans, with feeble constitutions forming a class quite distinct from those more fortunately situated in the outside world, and not to be readily contrasted, in their morbid tendencies, with average fairly fed children, at home

Morbid Anatomy —In the child the nature and extent of tissue disorganization in fracture are not identical with the adult As the degree of force necessary to break or crack the bone shaft is less, we will not [illegible] equently [illegible] sim [illegible] ration of conti [illegible] , as [illegible] cul [illegible] sse- ous [illegible] i [illegible] ic organic material there is rarely shattering unless, great crushing force acts over a limited area, the bone being less brittle, the double bladed spurs seen in the oblique fracture of an adult, are not encountered as the rent through the shaft is generally in a transverse direction. The periosteum being thick, and the muscular power comparatively feeble, marked displacement, over-riding of the fragments or surface deformity are not such prominent characteristics as in the matured man.

Joint implication constitutes one of their most serious features. Fracture through any part invested by the perichondrium on opening through the synovial membrane, or involving the "growing line," the epiphyseal bridge, in spite of what particular line of treatment is followed, may result in marked limitation of joint action, articular deformity, or permanent arrest of growth of the limb. It is probable that in all severe fractures, growth in the limb is in the abeyance, until after repair is complete.

In many cases of femoral fracture, shortening has been noticed by me, when perfect apposition of the fragments was effected, with ultimate solid union, without any deflection or bulging at the point of fracture, thus temporary arrest of growth was the only possible explanation for it. The shortening in some cases was slight, yet clearly apparent on measurement. Similar shortening occurs, after arthritic or osseous disease in children, and reasoning from analogy, we may expect to find it after fracture when there is long confinement in bed.

Fractures, or diastasis, contiguous to the arthritic structure give rise to difficulty in diagnosis and treatment, because of the copious, sanguinous extravasate into the peri-arthritic structures or the capsule and prompt diffusive inflammation, which so generally follows. At the complicated articulation of the elbow, the T fracture through the head of the humerus is almost certain to leave some impairment in motion. In the process of repair, there is sometimes a hyperostosis, with a pushing forward and outward of the trochlear hollow of the olecranon, resulting in a disturbance of the mechanical relations between the articular surfaces.

Diastasis through the epiphysis, when the extent of displacement is slight, in my experience, unites more quickly than osseous fracture. But, when this occurs under fleshy parts like the shoulder or hip in the delicate or strumous, its recognition is not only difficult, but it may lead to arrest of growth or impairment of joint action. Such results, however, are exceedingly uncommon. None have ever come under my observation.

In connection with this subject of diastases or fracture through joints, in order that judicious treatment may be instituted, an accurate knowledge of the condition existing is necessary, and here is where the difficulty comes, for oftentimes this is practically impossible, as every unbiased, experienced surgeon must admit.

In epiphyseal separation of the humeral head at the shoulder joint, although some writers of fertile imagination and remarkable descriptive power of what does not exist, have laid down *seriatim* the differential features between this and bone luxation. Jonathan Hutchinson states that all, or nearly all so-called shoulder-joint dislocations are but epiphyseal diastases. This is no doubt an exaggeration, though not far from the truth.

In either epiphyseal loosening at the shoulder-joint intra-articular fracture or dislocation in the child, although the anatomic elements involved are dissimular, the reactionary efforts are quite the same in all, hemorrhage, laceration of adjacent soft parts, inflammation, exudation with consecutive fibrosis and extensive adhesions in all or many of the overlying parts, occurs in each equally frequent.

Compound Fracture in Children.—In the present state of our knowledge and the great advances made in the surgery of the extremities, the time has come, when compound, comminuted or complicated fractures in children, should be separately considered and their distinctive etiology, pathology and treatment should be taught in our medical schools. Nevertheless, the antiquated and vicious system of dealing with all types of fracture, in the various epochs of life, on the same principle, is yet adhered to, even in our latest text-books on surgery. It has been noted, that the limbs, during the evolution of growth, are organically, totally, unlike those of middle or advanced age, being less firmly set, highly vascular and elastic. The lower extremities of the child carrying a lighter body are comparatively exempt from those shocks and jars inseparable from advancing years.

The recuperative energy of the osseous system of the child possesses marvelous activity, for it can not only repair, but also reproduce or restore shattered or destroyed segments of a bone-shaft. Therefore, by the aid of antiseptics and by utilizing those osteoplastic procedures so elaborated and graphically described by M. Ollier, we are often enabled to preserve limbs, sometimes so mutilated, as to seem to justify immediate amputation.

Morbid Anatomy and Pathology of Juvenile Compound Fracture.—Compound fracture is less frequent in the young, than in the adult for several reasons. The first is, at this stage of life the occupations of children are not so dangerous. Serious injuries most often befall them, however, through their venturesome tendencies and heedlessness. Proportionally for their volume, the solid elements of their bone shafts are better protected by the enveloping parts, which are highly elastic, as their fractures are mostly transverse, muscular action is weaker and the periosteal investment thicker, displacement after fracture is slight. The younger the living tissues the greater their resistance to the influence of pathogenic germs which may infect their protoplasmic elements, every thing else being equal.

Compound fractures only become grave injuries in a child, when the violence has been so great as to totally destroy the limb, or when large vessels have been opened and a considerable quantity of blood has been lost, as even moderate exsanguination in childhood is often attended with alarming shock.

The loss of a considerable area of integument by primary violence or secondary gangrene is a serious complication. The skin can never be reproduced, but frequently the bone can. The shock succeeding compound fracture in children is usually greater than in the adult, and the depression of the vaso-motor system is so pronounced that a marked pallor and depression of temperature pervade the entire surface of the body. Compound fractures which open into the joints, when sepsis is prevented and the vascular current is intact beyond, often do suprisingly well.

Several such injuries involving the elbow and ankle joints of children have been under my care

When there had been no loss of bone, whether the fissuring of bone extends into epiphyseal line or not, it is remarkable what a large degree of function is restored What frequently imparts a serious aspect in these cases is when the patient is strumous, and when inflammatory changes degenerate into widespread, suppurative infiltration, with sloughing

In all these cases of compound arthritic fracture, as in the simple variety involving joints, more or less inevitable displacement of the fragments, hyperostosis in callous formation and organized or semi-organized tendino muscular adhesions, for some time after osseous consolidation, more or less lock the joint and induce muscular atrophy In the youth, all of those pathologic conditions, as a rule so serious and often permanent, in the fully developed individual, are largely minimized in the ultimate effects by appropriate treatment and the innate tendency of the economy to restore adjustment and a large degree of function in an injured part

Treatment—This brief review of the subject will not permit anything like an extended notice of the subject of diagnosis, something which must always precedes definite specialised treatment, but to omit it altogether would be to vitiate, largely, whatever value the present contributation may possess It may be said, as a general rule, that fractures in children are most difficult of detection In fact in fractures contiguous with joints, it is sometimes quite impossible to recognize them In this class, the safest course to pursue is to proceed on the assumption that there is a fracture, and apply treatment It has been pointed out, that immediately after many fractures, tumefaction, sanguinous extravasate and muscular spasm, render examination severely painful, difficult, and sometimes indefinite More than once, when a case of injury, assumed to be fracture, has come under my care, when by moderate manipulation its detection could not be determined, I have made a show of adjustment and set the limb aside, under soothing dressings until the following day, when the real examination was made Almost invariably now, crepitus could be detected and the quality of the osseous disorganization ascertained with the infliction of no severe pain

Incision as an aid in diagnosis of fracture of a bone shaft is a procedure of questionable expediency Notwithstanding what asepsis may prevent in flesh wounds, when we deliberately open into a fracture of a bone shaft, we introduce fresh complications We at once make a simple, a compound fracture and expose the parts to the dangers of suppurative infiltration or necrosis In any other than rare and exceptional cases as a diagnostic resource, the incision should be condemned A practical knowledge of the general rules of diagnosis will seldom fail us without resorting to this extreme measure It is only necessary that the examination be made with gentleness and thoroughness, and when the suspected fracture be located contiguously with the shoulder or hip-joint, the patient should be placed in a position of complete muscular relaxation on a table or in bed, on the back In this connection it may be well to give a warning against the possibilitity of diagnosing fractures which do not exist

It certainly is no reflection on one's knowledge or skill when in doubt about the existence of fracture to frankly confess it to the patient, his friends or relatives, but it becomes a reprehensive line of conduct to decide alone, on a case and put up the limb in an apparatus or adjustment, for the cure of an imaginary condition Such mistaken cases have come under my observation in nearly all the long bone shafts, at the wrist and the elbow, the clavicle, scapula and neck of the humerus, the femur, the tibia and fibula

Pulmonary anesthesia is an invaluable adjuvant in diagnosis of various fractures It may be laid down however, as a law, *that when detection is only possible by this agent in the case of bone trauma, the extent of damage is not great, and the establishment of definite diagnosis will not materially effect treatment* It is very seldom necessary in the youth, and is not without its dangers We usually resort to it, in order to avoid the imputation of ignorance or neglect in complex cases, perhaps also as an aid in reduction or setting

Treatment—Simple Fracture—The limb of an infant or youth is more intolerant of protracted restraint or severe pressure than the adult, with him are commonly incomplete fractures, or non-displacement of the fragments, and hence not a few of them, are overlooked, or not discovered, until a large callus or deflexion attracts attention Although primary union of bone is prompt, the uniting bone slowly calcifies, and the tendency to bowing remains for some time after apparent union, at the sight of fracture

A mistaken impression prevails, that treatment of fracture should be instituted on the spot, *sur le champ*, as though the limb must perish or fall apart, unless it be at once placed in a rigid adjustment This view has often led to most disastrous consequences and calls loudly for the voice of a Pott, or of a world-famed luminary, like Senn, to condemn it

The aim to be sought for *immediately* after simple fracture, is to place the limb in a comfortable position In none is this more important than in the tender susceptible child Sometimes, this end is effectively accomplished by immediately setting the bones and splinting the limb, while in others the best splint is a bed, the limb well bolstered and enveloped in soothing dressings, until the following day or such time as the inflammatory disturbance has disappeared, tumefaction has diminished and muscular spasm has passed off Nothing has been lost by this delay, as the work of repair is impossible until the subsidence of local engorgement

The treatment of uncomplicated fracture limbs in general embrace but a few broad principles, which apply to all ages, they must, under certain conditions of age and environment be modified

After all severe fractures the system sustains more or less shock The body needs rest, no matter whether it be the upper or lower extremity which is involved The patient should *first* be treated, then his injured limb This should be comfortably adjusted, for if severe pain persist after the limb has been set, something is wrong

On Splinting—As there is seldom much displacement, if any, in several varieties of fractures in children, we will do enough in many cases at the first visit, to simply place the limb at rest without any other investment than a bandage, until after the primary callus is formed, when a support is adjusted to obviate deflexion in the ossifying stage Osseous apposition of the fragments with retention is desirable in those cases of fracture attended [illegible] much [illegible] placement

In order to realize this end or [illegible] dr ends of the bones into as convenient contact as possible and so retain them, we depend mainly on two or three things the first, the most important and more valuable than all others combined, is *muscular relaxation*, or postural treatment This permits unfettered liberty of the circulation, and the highest possible activity of the nutritive processes In the lower extremity, for the leg, the foot may be used as a counter-extending force, in the thigh, both the leg and foot In the arm, the forearm is the counter-extending weight With the child we have little to fear from bed-sores, and he bears enforced confinement with less impairment to health than many who after middle life accumulate additional flesh Desault was the father of the method of fracture treatment now so generally adopted, in which the principles of muscular relaxation is so generally discarded Long splints are applied and artificial extention is generally employed

To enter into the comparative value of various methods would involve a large task, which can not be undertaken here, but, after fifteen years experience in a large traumatic surgical service in hospital and a fair share outside, I am convinced that mechanically splinting and confining *all* fractures is an error that the results are not as satisfactory as they should be and that the time is not far distant when Pott's principles in fracture treatment will again reign supreme

But even now, in fractures contiguous to or involving the articulations, our sole reliance is muscular relaxation and postural treatment

Overlaying apparatus in joint fractures are little more than masks, which practically accomplish nothing They, however, fulfill a psychical affect, something often highly necessary with the fault finding and supercilious

Early passive motion, in my experience, is highly desirable in all fractures of children which involve the articulations Not a few distinguished surgeons are opposed to it, in my judgment very much to the disadvantage of the injured

Marked deflection of long shafts, after treatment is completed, very justly reflects discredit on the attending surgeon, when the child is constitutionally sound It is most frequently seen in the female

We may find that the patient has a lump of bone projecting outward where the shaft has the least muscular investment, the limb is very markedly shortened, and the patient walks with a limp It is not my intention to reflect on the surgeon for this blemish, for as a sequel of fracture treatment it may occur in the hands of anyone, only it should not be allowed to remain if of an aggravated type

It is surprising how easily it is overcome if taken in hand early The bone is then pliant and by the use of moderate force can be easily pressed into position, the bowing overcome and length restored Some of these cases of deflexion are dependent on an organic defect in the osseous elements, a species of malnutrition not well understood, in all instances, however, it is well to favor consolidation of the fragments by close attention to the hygienic surroundings, proper nourishment, tonic and reconstructive medicines

Massage, bathing, kneading the muscles and frequent changing the position of the patient are helpful aids, and as Championiere has lately demonstrated, entirely innocuous as disturbing agents of the approximate fragments

On the Treatment of Complicated Fractures or Open Compound Fractures —Although every fracture not attended with an open wound is designated "simple," under very many circumstances it leads to a wrong inference, hence it would seem both desirable and necessary that in every instance when the arthritic, neural or vascular structure, to a considerable degree, share in the traumatic disorganization of bone, the word *complicated* should be substituted for "simple" and the word *open* for "compound "

To the inexperienced the word "compound fracture" has a most serious significance, while as a matter of fact not a few of the cases embraced under this class recover with better limbs than the "simple" And, of the latter occasional instances occur, when the damage to the fractured limb is so great, as to, later, demand amputation or lead to a wasting or anchylosis of the limb

Modern measures, inhibiting germ infection, great advances in osteoplastic science, combined with perfected mechanical adjustment and prothetic devices, under no circumstances justify the sacrifice of a limb or a part of a limb after an injury in a child, unless the parts have suffered *total* death by violence

In open, compound fractures of the limbs our first concern must be to arrest hemorrhage This should be done as far as possible by exposure, ligation, torsion or immediate compression of the spouting arteries When bleeding is venous or parenchymatous, moderate tamponage and bandage pressure will answer for its suppression, but under all circumstances very hot water as a styptic or protracted elastic compression, with Esmarch's bandage, as a hemostatic agent must be condemned, the former for its destructive action on the vital structures and the protoplasm, and the latter, from the danger of gangrene following

Our next step is cleanliness and all that it implies in a strict surgical sense Now, we will endeavor to comfortably adjust the fragments and provide them necessary support, under appropriate dressings until general and local reaction is established In the average case of severe open shattering of bone, with more or less displacement and extensive mangling of the tissues, the safest course of practice to pursue is not to undertake too much at the primary dressing

From a theoretic standpoint this advice may seem untenable and injudicious

The parts, it is true, are now more or less benumbed, and may be handled with less pain, yet in all cases in which any tedious manipulation is necessary an anesthetic must be employed But in all these cases severe constitutional shock is present, muscular spasm drags on the fragments and infection is so constant that primary union seldom follows without suppuration and limited gangrene of the damaged parts

Better by far, in all very serious cases of this class to be contented with temporary adjustment of the mangled limb, secure against fresh infection and hemorrhage for at least twenty-four or forty-eight hours or longer, unless special indication call for a change

The question as to what we shall do with the displaced fragments to secure their surfaces in permanent contact, by wiring, pegging or riveting what fragments we shall return and what detach, how we shall place the osseous structures in position most favorable to regeneration, when there has been much loss of bone substance, belongs to the subject of osteoplasty, a branch of the healing art which every surgeon must familiarize himself with and master who would perform his whole duty to his patient As this subject is too large to be considered in this brochure, it is enough to say what my own experience long ago convinced me of, viz, that under no circumstances should any fragments of bone be removed that preserve an intimate attachment with the soft parts In the upper extremity our every effort should be strained to preserve every possible particle of bone tissue that possesses a cutaneous investment, and no excision or division should be done through any other than parts hopelessly devitalized

Modern prothetic appliances have done much to substitute a sacrified limb, at least for appearance, though as an appendage for the lower extremity they sometimes support the body and carry it, nevertheless, let no one deceive himself into supposing that any artificial support can ever fulfill the purposes of a natural one, and needlessly sacrifice any part of the lower extremity

There are several reasons why a severe fracture through any part of the lower extremity is more difficult to treat than in the upper It is here where fracture is very common, and in railway or other serious accidents the greatest extent of mutilation is inflicted Yet, when we can provide proper attention to a case it is surprising what results we may realize in many of the frightful cases of bone disorganization

As an example I might mention one case of open fracture in a child of 6 years, run over by a street car, in whom the entire tibial shaft was so shattered that it was entirely shelled out through the long breach in the tissues Only the epiphyseal ends and periosteum remained In one year this entire shaft was regenerated, there was no shortening and no limping In another, a young adult, the bones were so smashed that a little more than four inches of the shafts of the tibia and fibula on damaged side had to be removed, and the widely separated ends pressed together In six months union was complete By a rise on sole of shoe shortening is compensated for, no crutch or walkingcane is used and last autumn he won a wager, walking from One Hundred and Twenty-fifth Street, in Harlem, to Coney Island, a distance of about twenty-one miles, leaving Harlem at 6 in the morning and returning before 6 in the evening This he accomplished with ease

We can secure surprising results in most any description of fracture in the leg of a child, below the knee, provided the circulation be intact, but when the fleshy parts are torn open in femoral fracture, we have good grounds for the most serious apprehension

The extent of shock is always very great, in compound, femoral fracture, and in most cases there is considerable loss of blood before efficient surgical care can be rendered In spite of anything that we can do to prevent it infection will set in and spread, always endangering life through infiltration, resorption and pyemia

There are several varieties of fracture of common occurrence in the adult, rarely or never seen in the child In them I have never seen a fractured patella or a Pott's fracture One instance of intracapsular fracture at the hip has come under my care, in a youth of sixteen years Subsequent to the injury necroses of the surface of the distal fragment developed and provoked suppuration On incision through the anterior plane of muscles, the capsule was opened and the neck was cleared away and the head left The operation was performed four years ago The patient is now a full-grown man with a very useful limb, except for about three inches shortening

I never yet met with a case of Colles' fracture in a child, although some authors speak of it occuring during the stages of growth I doubt their accuracy of diagnosis Colles' fracture almost invariably leaves deformity through rupture of the internal lateral ligment and displacement outward of the head of the ulna, impaction and diastasis of the radical head

Deformities, therefore, should be rarer after juvenile fracture, functional restoration better and restoration of strength greater after treatment than with those approaching or after the meridian of life

In conclusion, as far as treatment is concerned, it may be said that as applied to so-called "simple" fractures, or the complicated, involving the joints, in the child there has been no special progress made in late years, the mechanical problem is not settled and our best authorities are not in accord on the question of attitude or position of the limb, on immobilization, extension and counter extension The fact is, that mechanical aids in fracture have but a limited application, as we are dealing with a living machine not subservient to any physical laws in its vital processes

Enduring progress only has been made with the complicated and open fractures, in which, by adoption of antiseptic methods and osteoplasty, safe conservatism is possible and now we are enabled to preserve limbs formerly condemned to amputation or a crippled condition, which rendered them little more than useless

DISCUSSION

Dr Ella E Barnes, Birmingham—I would like to ask Dr Manley if in the German boy there had been a growth of the other limb sufficient to make the shortness appreciable?

Answer—About an inch

Dr Barnes—Will time ever overcome that by the extra use of that limb? Suppose a high sole were put upon the other limb and this limb allowed to swing, will the shortened limb ever become longer?

Answer—I am not able to inform the Doctor As far as my experience goes, there is no remedy for shortening We know that the limb would stop growth during the process of repair

Dr Daniel H Cunningham, Chicago—I would like to ask Dr Manley the manner in which he applies his splint, or what splint he uses to keep the limb quiet and prevent the edges of the bones causing laceration

Answer—I have nothing special I adapt treatment to each individual case Some families can afford splints and others can not We should not wed ourselves to any particular splint in the adjustment of the limb

Dr A C Cotton, Chicago—I want to ask Dr Manley would he make any objection to blanket splints?

Answer—They are excellent

Dr Manley—We have to consider the matter of expense There has been devised a splint made from strawboard which acts admirably in children It is very light and can be easily cut down with the knife, and by submitting to hot water it softens and you can shape it to the limb I think it is about fifty cents a sheet and a sheet is enough to make about a dozen splints If I could not get anything else I would use plaster of Paris, but I do not believe there is anything else has given us so many cases of distortions and deformities When you remove it you have to give the limb more or less jar to get it off The chewing with the knife, or whatever it may be, causes more or less jarring of the limb, and you can not put a plaster on the limb from which the limb will not fall away and the dressing will become loose Particularly in fractures of the forearm in children it is important to inspect the limb every day I have known plaster encasements, in which there was no rise in temperature and everything seemed to be going on splendidly, but after ten days when we cut down through the plaster, both bones were found projecting through the skin, and black So I believe the plaster has a very limited use in children It is unyielding and you might just as well put the limb in a vise, and after considerable disorganization of the soft parts, in fracture, there is a great deal of tumefaction and it is important there be room for this The plaster simply puts the patient in torture When a fracture pains there is something wrong about it, but with the plaster applied, we have to cut down through the hard, rigid plaster, shaking and jarring the limb and causing more pain than ever I have a positive prejudice against plaster, except in occasional cases

Dr J A **Work**, Elkhart, Ind —I have had some cases where I did not expect to save the limb, more particularly the fingers and toes, and I am glad to say the results were so good I am ready to attempt to save almost everything As to splints, I use almost exclusively the binder's board What do you think of the binder s board, Doctor?

Dr **Manley**—I like it very well

Dr **Work**—It is soft and pliable while wet and you can adjust it very well, indeed You can allow for distention, while the inflammatory process is going on, and after the inflammatory process you can retract the splints to the limb If you have a perfect cast of the limb, you have your limb in perfect shape I think the wet splints have a tendency to keep down the first inflammation

Dr C G **Slagle**, Minneapolis—Dr Manley has spoken of the shortening, which might sometimes help us out in suits It appears to me that if the child is confined to bed two or three months, the sound limb would grow rapidly while the growth of the affected limb would be largely suspended I have been surprised sometimes at the shortening but this explains it nicely As to setting the limb, the Doctor is very conservative But I suppose, Doctor, if you were called immediately you would set the limb, but after the swelling began you would not do so until the swelling subsided

Dr **Manley**—As the first principle we should put the limb in a comfortable position, and that would imply setting and leaving the limb in a temporary dressing, not putting the permanent dressing on until the swelling is over

Dr A C **Cotton**, Chicago—The remarks have brought out that no absolute rule can be devised or laid down to fit surgical procedures We should let the limb alone and put it in a comfortable position, if only on a pillow If we want union by first intention, the ends of the bones must be approximated, nicely coapted Although we get relief from pain by putting the limb in a comfortable position, unless we approximate the end of the bones we will not get primary union We might have a dozen cases without that condition, while in the thirteenth it might be found A whiff of chloroform could be given, the ends approximated and a splint applied The Doctor expresses my views of those of plaster of Paris dressings I suppose the orthopedic surgeon, with the necessity for rigid retention apparatuses, could hardly get along without the plaster, but he does not have swelling we have to deal with

---

Rhinopharyngolith —This is the name given by Janatka of Prague to a body removed by him from the naso pharyngeal cavity of a nine year old boy It was found to consist of a tailor's thimble, which the child was supposed to have swallowed when he was one year old, and had thus remained imbedded in the nasal cavity for eight years, considerably disintegrated and coated with calcium carbonate and calcium phosphate It had caused difficulties in breathing and hearing, and a tumor had been diagnosed —*Wiener Klin Rundschau*, September 20

OBSERVATIONS IN CASES OF EPILEPSY FOLLOWING INJURIES TO THE HEAD IN INFANCY, CHILDHOOD AND EARLY YOUTH

Read in the Section on Diseases of Children at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5 8 1896

BY W A DIXON, M D

RIPLEY, OHIO

In introducing this subject, the purpose is to express my convictions arising from observations in my own practice that great care should be used in rearing children, that the head may not receive injuries, lest epilepsy follow as a result

During my first years of practice I had no conclusions of my own as to the liability of epilepsy to follow injuries to the head in early youth, and sought to discover in each case presented to me a cause in heredity, reflex irritation and the many other causes given in the text books

In after years, however, when the child that had received injury to the head was brought under my care on account of epilepsy, the importance of this subject became apparent to me

I can cite a number of cases whose history I am personally familiar with from the date of the injury received to the development of the epilepsy

I take no censure to myself in the treatment of the injuries at the time of their occurrence, because epilepsy developed in after-years, and cite the following cases, not to speak of treatment or of the character of the lesion, but of the fact that epilepsy did follow the injury and in the absence of any other known or suspected cause, must be considered the reasonable source in each case, and therefore that physicians should be under obligations to teach parents and others in charge of children the necessity of guarding against all injuries to the head that epilepsy may not follow as a result in after-years when the brain develops, the sutures unite and expansion or growth of the cranium ceases

Case 1 —J R , a boy aged 5 years, was kicked by a horse, fracturing the left parietal bone There was depression and symptoms of compression The fragments were removed, the depressed bone elevated The boy rapidly regained consciousness and made a good recovery with nothing to indicate that he had received so serious an injury At the age of 24, when he had attained to full growth in body and mind, without any premonitory symptoms he fell to the pavement in a fit of epilepsy His condition rapidly grew more and more grave, so that in two years' time he consented to an operation of trephining in the hope of finding relief Dr P S Conner trephined, finding beneath the site of injury within the membranes a cystic tumor large as a medium sized orange

Case 2 —W K , aged 6, was kicked by a horse on the frontal bone over the left eyebrow, causing slight depression with symptoms of concussion but not compression He made a rapid recovery and exhibited no results of the injury, until arriving at the age of 20, he was seized with epilepsy, which continued to become more and more aggravated during the three years following, when he died from exhaustion

Case 3 —G M , aged 10, was kicked by a horse in the middle of the forehead, fracturing and depressing the bone, causing deep coma The fragments of bone were promptly removed, and the depressed portion elevated The coma was quickly recovered from Recovery was rapid, with no evidences of the injury remaining At the age of 20 epilepsy developed He is still living and the victim of frequent attacks

Case 4 —L P , aged 8, was thrown from a horse, striking the crown of the head upon a small stone in the road There was laceration of the scalp over the left parietal bone, and slight depression but no symptoms of compression, and no line of fracture could be determined Recovery was prompt At the age of 28 epilepsy developed The paroxysms have continued to increase in severity until now the patient is a complete physical wreck

Case 5 —W B , a boy aged 12, stopped on the sidewalk to tie his shoestrings On attempting to set one foot on a step, the other slipped from under him, causing him to fall backward, striking the occiput violently on the pavement There were symptoms of concussion, lasting several hours In a short time epilepsy developed and continues to the present in an aggravated form

Case 6 —J F , aged 8, fell from a swing, striking the head upon a stone, lacerating the scalp and producing symptoms of shock which lasted several hours There were no symptoms of compression nor fracture Recovery was apparently perfect At the age of 18 epilepsy developed and continued for about three years, becoming more and more violent until death

Case 7 —J R , at the age of 5, fell from a fence, receiving a blow upon the head, producing violent shock, and was in a state of stupor for several days At the age of 16 epilepsy developed and continues to the present

Without reciting each case similar in most respects to the foregoing, I can call to memory many other cases of injury in whom no history of heredity, specific disease or reflex neuroses of any character whatever can be traced as a cause

Younger children, in my judgment, are in danger of epilepsy upon meeting with what may be termed every-day casualties, as falling down stairs, out of the high chair, off the bed to the floor from the porch to the pavement and other similar accidents where the head receives the blow

I can recall quite a number of epileptics in boys and girls to whom I was called at the time of such accidents as spoken of above at the crawling age of childhood Some of the worst epileptics I have seen have no history of cause beside the fall and consequent injury to the head of the infant

Meddlesome midwifery, it is to be feared, must be held responsible for some cases, the most wretched and hopeless we are called upon to witness, the forceps having inflicted injury to the head

Prof Chas D Meigs in his day, foreseeing the tendency to wantonly use the forceps, charged his pupils to remember that the best obstetrician was he who stood by his patient with his hands folded behind him

There are dystocias when the forceps must be used, when it would be criminal to not use them, though epilepsy in the child be sure to follow The point is this, that the utmost skill and care should be used to avoid injury to the fetal head lest epilepsy may develop in the child

I have seen two cases, not my own, it is reasonably certain resulted from injury in forceps delivery, and two more strongly suspected to owe their origin to the same cause, every other history of cause being absent

My experience is largely among rural people where the forceps are not often required or resorted to, and where of course epileptic results would be rare from such a cause, but if two cases come under the observation of each city and country physician during a quarter of a century, see what a vast army of epileptics follow in the wake of the forceps Epilepsy merits the attention of the physician from every standpoint Large numbers of epileptics are in every locality They are of all people the most unfortunate Too much can not be known concerning it How impotent all physicians confess themselves to be when confronted with it

In cases from trivial reflex causes treatment may be successful In confirmed cases medicines avail so little that both physician and patient tire of treatment

The surgeon on account of so small percentage of favorable results in the most hopeful cases operated upon is held at bay So the most rational procedure is to adopt preventive measures

If heredity, insanity, inebriety, specific infection and so on among the ancestors are found to be causes, the gravity of the affection demands that means be employed to curtail the transmission of the disease to posterity Knowing injuries to the head to be a fruitful source, all should unite every effort to teach and impress upon parents and others in charge of children to use all precautions possible to protect the child's head from every sort of injury, epilepsy having been known to follow what seemed to be a slight injury to the head It is not the purpose to speak of any theory of pathology or morbid anatomy

The literature upon the disease is enriched by the observations of eminent men in every age and country The same views are not long held by any student, for experiments and postmortems are likely to revolutionize any theory previously announced

Most writers regard traumatism overestimated as an exciting cause Experiments of any kind that disturb the cardiac or cerebral functions may excite convulsions and establish any theory desired

In relating cases I selected those in whom a record in the ancestral line, of heredity, insanity, inebriety, tuberculosis or specific infection did not exist, so that the fact of injury alone could remain as the factor, the kind of injury that can be in a great measure avoided by watchful care in the rearing of children

---

PETIT MAL IN CHILDREN

Read in the Section on Diseases of Children at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga May 5-8 1896

BY LOUIS FAUGERES BISHOP, A M , M D
NEW YORK

Idiopathic epilepsy is eminently a disease of children, occuring in more than three-fourths of the cases before the twentieth year So much is this true, that in epilepsy in older people, we always institute a special search for a local cause Of the causes of epilepsy we are not to treat in this place, nor indeed of the typical severe cases, but because we separate petit mal, we must not fall into the error of supposing we have to deal with a different disease Nor is it always easy from the description of parents, when there is no opportunity of observing the attacks, to be sure into which group the particular case should go

Though not a common form of manifestation of epilepsy in children still among a large number of cases there will be a certain number in which the disease at least in its onset takes this form On account of its comparative rarity and because of the proneness of young children to convulsive attacks of various kinds whose etiology is clearly to be found in local irritation, these minor attacks of epilepsy are seldom recognized by those whose attention has not been particularly called to the subject

There are certain physiologic considerations that must have weight in our diagnosis Up to about three years it is difficult to make the diagnosis of petit mal because the physiologic irritability of the nervous system is so great that we can not exclude a sufficient cause of irritation After about the of
three years the nervous system has ob a
or stability that makes the frequent
vulsive seizures an indication of epi
if there is a family history of a t

attacks at a later period, which have not proved to be epileptic, this circumstance must be given due weight. As in older people we must exclude kidney disease and injuries to the brain.

In addition to a due appreciation of this period of irritability we need to have a more symmetric comprehension of epilepsy. Petit mal is not one disease and grand mal another, but they are different manifestations of the same disease. It is for the sake of emphasizing petit mal to the dignity of true epilepsy that this study of that particular form of epilepsy in children has been undertaken. The attack of petit mal is a sudden temporary unconsciousness, often accompanied by certain other phenomena. In a large number of cases the eyes become fixed, the face pale, and in a moment the patient assumes his ordinary conditions; in others, the patient talks in a wild manner, often upon some subject entirely disconnected with the surroundings present. The patient may perform some curious automatic action, or go through with some particular act while in the epileptic state.

A very curious case came to the Vanderbilt Clinic, New York City, a few days ago. The child, 7 years old, had frequent attacks in which she suddenly seized her head by the hair on either side and then there was a jerky motion of the arms and head, at the same time one foot was raised as high as possible and the child would stand for a moment on the other, but if not supported, would fall. This occurred while under observation about every fifteen minutes. The child was unconscious during the early part of the attack, which lasted probably during the fraction of a minute. Another child also seen at the Vanderbilt Clinic recently, suffered a compound fracture of the skull a years ago. A few weeks ago she developed attacks which come on every night about ten o'clock, after she had been in bed an hour or two. She wakes out of her sleep in a fright, and almost immediately becomes rigid and apparently unconscious.

An attack of petit mal may assume a great variety of forms. A mere momentary blurring and loss of consciousness at frequent but irregular intervals, or sudden sensations of fright without apparent cause, or a feeling of something in the epigastrium and rising in the throat. Thus in a case coming under observation while preparing this paper, a child of five years old had convulsions during the first two or three months of life, and since that time had been subject to attacks at intervals, the mother says "a thousand a day," during which the child's head suddenly drops, the arms are stiffened, and after an attack of momentary unconsciousness the child goes on as before. Such a case is of sufficient severity to attract the attention of a physician, and to make a diagnosis perfectly easy, but it can be seen that attacks of the same nature occurring at infrequent intervals, and of which we have only the account of parents, would nearly always be disregarded. When associated with *grand mal*, or when it has been followed by *grand mal* later on, the diagnosis of true epilepsy is of course very much more certain; still when studied carefully these cases assume a certain definiteness, which it is hard to convey by a written description.

The diagnosis must rest on the recurrence of the attacks irrespective of gastric irritation, the fact that they are not cured by the removal of sources of irritation, the persistence of the type of the attacks and the occasional recurrence even in quite young children of the epileptic equivalent, *i. e.*, periods, during which instead of loss of consciousness, the patient does and says things entirely disconnected with the time and place. The attacks must be distinguished in very young children, first of all from convulsive seizures due to local irritation. As we said before, under three years except in very well marked cases this can hardly be done.

Simple vertigo may resemble petit mal but the affection of consciousness is usually described as somewhat different. In vertigo there is a characteristic feeling as if objects were whirling around. The child says, "the house is going around." In epilepsy there is more the sensation of simple blurring or confusion. Vertigo is preceded by a period of weakness, while the onset of petit mal is always sudden. The patient is stiff for a moment, stares, and there is a momentary loss of consciousness, but the attack passes over as suddenly as it came, and he goes on with the occupation in hand. In vertigo the body is limp and the process is more gradual. In petit mal the pupils are dilated and the eyes immobile. We must distinguish hysteria, which occurs frequently enough in children. This may be done by the tightly closed eyes, the tremulous lids, the persistent rigidity, but especially by the existence of hysteric attacks of other types. Petit mal may occur every few moments for years without changing its form of attack. Of course, this rule is not without exception. Thus in a young person at present under observation attacks of petit mal are sometimes replaced by short outbreaks of ill temper, which are entirely foreign to her ordinary disposition.

While we have begged the question of a certain diagnosis of petit mal during the first three years of age, yet cases from time to time have come under observation in which a study of the particular case has convinced us that it was one of true epilepsy. Its frequency during this period of life is shown by the statistics of Gowers, who found that 12½ per cent of all epileptics had developed the disease *before three* years, and of these one half had developed during the first year of life. In our own histories we find fairly frequent instances of fully developed epilepsy in later life having originated as petit mal in children. This history is brought out more often if, as with us during the last few months, we have inquired particularly for symptoms of petit mal antedating the onset of convulsions. It would seem especially interesting to inquire as to the early existence of petit mal, in those cases in which under treatment, petit mal is substituted for the typical severe convulsions. Some of these cases impress one as if the attack of petit mal was a development of an epileptic aura, which stopped short of the convulsion. In some very rare cases there has been a distinct sensory aura preceding the attack of petit mal.

Petit mal is essentially a chronic disease, and for that reason it is difficult to formulate the best plan of treatment. However, special stress should be laid upon the care of the stomach and all those measures which are included under the name of hygienic management. As to drugs there has been a great variety recognized. Petit mal is more intractable than the severer convulsions, but the same treatment which has been found best in these has on the average given the best results in petit mal. After experimenting with a great variety of drugs it has seemed that bromid in moderate doses has given on the average the best results. Occasionally a case has shown improvement when under nitro glycerin Belladonna in our hands has never given any results, and the same is true of borax, digitalis, and a number of other drugs

If our conception of epilepsy as a stormy and ungoverned discharge of the motor cells of the brain be a true one, which belief is strengthened by the fact that seizures are more likely to take place in those who have been sleeping, or who habitually sleep too much, why would it not be possible by systematic training of these cells to diminish the liability to such outbreaks? Systematic exercise of such a varied kind as would exercise all the muscles of the body might thus have such an effect beyond that due to the mere improvement of the general physical condition

The parents of the child should know of the very possible persistence of the affection into adult life, so that everything should be done to render the disease as bearable as possible to the little patient The friends and attendant should be instructed to speak as seldom as possible of the attacks to the child, and should be thoroughly instructed that attacks of petit mal are entirely beyond the control of the patient An effort should be made to treat the child as nearly as possible as other children, not restricting it of its liberty, or treating it like an invalid in any way, except as far as is necessary to carry out the proper regimen and treatment

DISCUSSION ON PAPERS OF DRS DIXON AND BISHOP

Dr **Thomas H Manley**, New York—You know how unsatisfactory and discouraging the teaching of obstetrics to the medical student has been It has often occurred to me it would be better for humanity if we had no such science as the art of midwifery You will remember it was claimed the mortality from sepsis had been reduced to practically nothing, through the adoption of the antiseptic treatment, washing and flushing the vagina precedent and antecedent to confinement, and then, again, we have been taught later the position we are coming back to, the best thing to do is to do nothing at all in the way of using solutions about those passages The tendency is, that the ideal man is the one who can make a diagnosis without passing his finger in the vagina Then we will not have to deal with a sepsis, because pathogenic germs do not normally belong in the vagina When the forceps are used damage may be done in the way of lacerations and tears of the cervix, vagina and outlet, so far as the woman is concerned, by not allowing nature to gradually open the way and send the child along by slow and natural stages Next, with reference to the child, I think the effect of the forceps is murderous, perhaps not at first but ultimately You can not make me believe the strength of a man with the forceps locked on the fetal head, and perhaps a couple of women holding the women in the bed, will not injure the delicate structures of the fetal brain In my own family, the only one who has manifested any nervousness, and now she is an adult, was the first born, in whom I believe the physicians prematurely applied the forceps and damaged the head I would not allow the forceps to be used on any of the others and they have no bad symptoms

Now as to trauma as a cause of epilepsy That has not been my experience, and for fifteen years, I was connected with a hospital in which traumatisms constituted perhaps four fifths of the cases In New York we have thousands of cases of traumatisms, from children falling from the fire escapes We have, consequently, many cases of skull injuries, but my experience has not been that trauma in itself is a cause of epilepsy I have traced quite a number of cases, where it became necessary to trephine and elevate depressed bone, the children had been brought in the ward perhaps unconscious, and I could not find in enough of cases the history pointing to trauma to convince me it was a positive etiologic factor in epilepsy as a general rule

As to the surgical treatment of epilepsy, I have trephined quite a number, who had come into the hospital for that special purpose After Professor Horstley's paper, which did great damage from claiming he could do what could not be done, I hoped something might be done for the epileptics and I trephined In perhaps about a quarter of them I found those gliomatous tumors, the myxomatous substance between the dura mater and pia mater Not in a single instance was there anything but temporary relief I believe there is a question whether the relief was from the loss of blood, the opening of the scalp, the anesthesia, the psychic effect of the operation or what If there is anything we owe to each other it is to be truthful We can not get the facts unless we get the cases that do badly as well as those that do well, and I have not hesitated to go before my optimistic brethren in New York and ask them to show me one case which showed relief from operation But if we have evidence of distinct depression of bone, it is very clear what the line of action should be But otherwise I doubt the expediency of operation We should not overlook the fact that these operations are not entirely innoxious I have known more than one patient to lose his life from hemorrhage When you start a hemorrhage in the brain, which is an extremely vascular organ, you can not stop it readily You can not apply pressure without pushing a hole through the brain substance

Dr **J A Work**, Elkhart, Ind —One point came to my mind during the reading of the first paper The author did not say much about etiology in petit mal in children It seems to me we ought to determine the primary cause of all this trouble He said we should look well to the condition of the child's stomach, to the development of the child, to its food, its environments It seems to me there is where the trouble originates in early infancy or childhood, when we consider that one half of the deaths that occur are in children under 5 years of age I say the same of the second paper read We do not go back far enough in etiology It has been my fortune to see cases of epilepsy that have orignated traumatically I would like if the Section would permit the time, to report one or two of these cases One case was that of a soldier, on his way from Indianapolis to another point, who fell off a flat car and was not found for two or three days When found, he was suffering from depression, I think in the right parietal region The history of the case was that the patient was unconscious for probably twenty four hours The later history of the case I had from his own lips After returning from the army, although a molder by trade, he went into the study of law, about fifteen years after the injury, and he said from the time he recovered consciousness until I was in conversation with him he had not been void of pain in the region where the injury was received, except when he was asleep I was called one morning early He had gone to the cooking room to build a fire and was later found on the floor This was the first attack he had had of epilepsy, some fifteen to twenty years after the injury He seemed to recover as if he had awakened from a sleep, and wanted to know where he was, how he came there, etc The attacks became more frequent, and he became more imbecile and died about two years after the first attack A postmortem was held Under the dura mater, at the base of the brain, we found a tumor about the size of a turkey's egg, flattened out, which we supposed was the cause of the epilepsy and death

Another case was that of a soldier injured at Chickamauga by a shell He lay on the field for some hours, and the surgeons pronounced his case hopeless He fin recov d and served out his term in the army But h on his forehead in the injured region, wo insensibility After his return home, laborer, he fell down with epilepsy, and found he could not obtain employment because of his attacks, which occurred every two weeks I saw him have an attack near my office I thought he never would never recover from it In two weeks, after preparatory treatment, I trephined and removed a three quarter inch disc No evidence of fracture of the skull was found The skull was very thick In two weeks from that time he had a slight attack and that was the last He died some ten years afterward of another disease There was a case of cure, to all intents and purposes, by trephining

Dr Harold N Moyer, Chicago, Ill —I can not allow the *opportunity to pass without making a remark* or two upon the papers with reference to epilepsy This disease is one of the most interesting in our pathology I think we are apt to forget this is the morbus sacer, the sacred disease of history I believe epilepsy is the oldest disease existing I believe it began when the animals began to have nervous systems Animals have the disease, cats are notoriously affected with it, horses have it under the name of "blind staggers," elephants have it without a doubt, and how far down the scale it extends it is impossible to say It probably existed prior to the stone age, even prior to the time when man made his advent upon this earth We understand it now no better than they did then We absolutely know nothing about the pathology or the pathologic anatomy of epilepsy We know nothing as to its etiology, more than the exciting causes which have been mentioned Head injuries, the importance of which has been well brought out, I consider furnish many cases of epilepsy There are doubtless many other causes, but it is well to remember these are merely exciting causes Many children receive injuries who do not develop epilepsy Why do those who receive these injuries not have epilepsy? The difficulty is that the underlying etiologic factor in epilepsy is absolutely unknown to us If we understood that, we would know its pathology When we come to the question of treatment, the same thing applies, not knowing the pathology and etiology, the treatment must necessarily be vague But I wish to emphasize the statements made by Dr Manley Operations for epilepsy undertaken indiscriminately because the patient is epileptic, should be discouraged I believe it is almost malpractice to operate in these cases, for you thereby add a very severe trauma I want to be understood in the proper sense, for it would not be malpractice if the operation is demanded by some injury, depressed bone, etc But otherwise I have never recommended skull operations except in the form known as Jacksonian epilepsy where the center could be well localized I believe the literature of the subject justifies very strong statements on this question

The paper by Dr Bishop is very interesting The Doctor was kind enough to give us his diagnostic rules I confess as I listened to him I thought I would be able now to make a *diagnosis of* epilepsy in childhood with some precision, but I fear I will not be able to apply the lines he has laid down But there is one good rule, which I shall substitute for those given by the *Doctor, and* that is if I have brought to me a young child in which I suspect epilepsy, I shall assume it is epilepsy and treat it as such If it is not epilepsy, such treatment will do no harm, and *if it is epilepsy in its incipiency,* then is the time to do good with treatment If there is any one rule in this disease, it is to begin treatment early After the condition is confirmed, treatment is almost entirely hopeless The petit mal is then more hopeless than the grand mal, because the petit mal is accompanied by changes in the brain which lead to early dementia and conditions leading to imbecility Unfortunately, the treatment is not all that could be wished I desire to emphasize the Doctor's remark, that the hygienic treatment is of the greatest importance As to the medicinal treatment, I am a firm believer in the bromid of sodium and use no other salt I do not mean to say that you should simply pour in this remedy and you will secure good results, for one third will not tolerate it, another third will be benefited, and another third will be indifferent to the treatment But I believe this bromid is better than any of the others, and it is much better borne than the bromid of potassium If it is given two hours after meals and well diluted, and the patient is frequently bathed, very considerable doses can be given without producing bromism The bromid of sodium given within the tolerance of the patient and begun early I believe is the most efficient treatment

OPTIC NERVE ATROPHY FROM TOXIC AGENTS

Read in Discussion on Optic Nerve Atrophy in the Section on Ophthalmology, at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga May 5-8 1896

BY G E DE SCHWEINITZ, A M, M D

PHILADELPHIA

Toxic optic nerve atrophy naturally includes, 1, those cases of atrophy which result from a direct action of the poisonous substance, or its systemic results, upon the nerve cells, the nerve fibers or their *vascular supply, and,* 2, *those cases of atrophy* which are secondary to retino-choroidal or constitutional changes, which in their turn have been called into existence by toxic agents

The first class is separable into three subdivisions, namely, *a*, partial atrophy of the optic nerve with special reference to degeneration of its papillo-macular bundle, *b*, scotomatous atrophy of the optic nerve, which is progressive and may become total, and *c*, general atrophy of the optic nerve

1 Toxic atrophy of the papillo-macular bundle of the optic nerve preceded by inflammation or degenerative changes in this tract and associated with scotoma—Cases of this class manifest themselves either in the form of a chronic retro-bulbar neuritis, or else as an intoxication-amblyopia, because we may with propriety draw a clinical distinction between these two manifestions, although anatomico-pathologically they are in close accord, the intoxication-amblyopia, as Groenouw puts it, being a special form of retro bulbar neuritis

Axial neuritis, a term sometimes employed according to the same author, should be reserved for those cases characterized by a lesion, confined to the papillo macular bundle where it is axial in its course

Following Groenouw[1], the papillo-macular bundle may be described as consisting of those fibers in the optic nerve which supply the retina between the macula lutea and the papilla, and which lie in the temporal portion of the nerve tip, in a wedge-shaped segment The apex of this triangular portion is directed toward the vessels and occupies about one third of the surface of the papilla As it pursues its way through the orbital portion, it gradually approaches the axis of the nerve, which it reaches in the optic canal At the foot of the chiasm it occupies its upper and inner portion, but in the tractus it sinks to the central portion and remains there until it arrives at the brain

According to Sachs[2], the papillo-macular bundle in the papilla is a triangle with its apex at the vessels, and the base toward the supero-temporal quadrant Going backward, the bundle becomes elongated and assumes a crescentic form as it nears the optic canal

It would not be profitable at present to discuss the differences of opinion as to the disposition of these fibers in the optic nerve trunk, in the region of the vessel-entrance, and their division in the chiasm For their full consideration the reader is referred to the examinations of Samelsohn,[3] Vossius,[4] Nettleship and Edmunds,[5] Uhthoff,[6] Bunge, Sachs[8] and Stöltzing[9]

---

[1] Graefe s Archiv 1892 xxxviii Abth I pp 1 70
[2] Archives of Ophthalmology, 1889 xviii No 2 pp 133 162

Upon this papillo-macular tract the baleful influence of certain toxic agents falls, and there result an augmentation of nuclei, a hypertrophy of the connective tissue and a wasting of the nerve fibers, the process being most intense, according to Sachs, in one small area, which he calls the "nuclear group" There is, in fact, an interstitial sclerosing inflammation comparable, according to Samelsohn, to the same pathologic process visible in interstitial hepatitis[10]

Some difference of opinion exists as to the exact nature of the nerve changes By certain observers the inflammatory nature of the process has been emphasized, by others (Sachs) its degenerative character To quote from Sachs, the diseased process starts in the interstitial connective tissue and the nerve fibers suffer secondarily from pressure, in the same manner as the hepatic cells are destroyed in cirrhosis of the liver The vascular changes of the two affections are also analogous, and, according to Sachs, there may be found "not only a proliferating endophlebitis, leading to connective tissue obstruction of the vascular lumen, but a peri-phlebitis, resulting first in a choking of the peripheral capillaries and afterward in small extravasations from them"

The pathologic lesions thus briefly described are based upon the results of about sixteen autopsies The most important of these are as follows

1 Samelsohn[11] The patient suffered from double retro-bulbar neuritis, which began with the clinical picture of an intoxication-amblyopia, the central scotoma being at first relative and later absolute death resulted from chronic heart disease The abuse of tobacco and alcohol was not substantiated

2 Nettleship and Edmunds[11] The patient was a diabetic and an excessive smoker The fields of vision were normal and in each there was a nearly central scotoma for red Death resulted from carbuncle

3 Vossius[11] The patient suffered from alcohol-amblyopia, had at one time a central scotoma, and died hemiplegic and aphasic

4 Bunge[11] The patient was a tabetic and also probably under the influence of tobacco and alcohol

5 Uhthoff[11] (Six cases) The first patient was a chronic alcoholic, with marked blanching of the temporal halves of the papilla, but without record of scotoma, who died from the effects of alcoholism The second was a patient with atrophic discoloration of the temporal halves of the papillæ, absolute central scotoma, who died in an attack of delirium tremens from intercurrent pneumonia The third was a patient with atrophy of the temporal halves of the papillæ, who suffered from delirium tremens succeeded by dementia paranoica and died a lunatic It was not possible to test the visual fields The fourth was a chronic alcoholic who died of meningitis during an attack of delirium tremens No visual fields were obtained, but the temporal halves of the papillæ were atrophic The fifth was a confirmed drunkard, with atrophic papillæ but without demonstrable color scotoma, who died phthisical, and who suffered also from interstitial hepatitis The sixth was a drunkard with atrophic temporal halves of the papillæ without defect in the color fields, who died of pulmonary edema supervening on general paralysis of the insane

6 Wildbrand[12] The patient suffered from polyarthritis and central scotoma which developed suddenly, death resulted from cardiac failure

7 Theodore Sachs[13] The patient was an alcohol-tobacco amblyopic, who had typical central scotomata and who died from intercurrent pneumonia during nephritis

8 Stoltzing[14] The patient was a tobacco-alcohol amblyopic, who died from pleurisy, fatty heart and atheroma of the aorta, scotomata are not mentioned or described

9 Theodore Sachs[13] The patient was believed to suffer from intoxication-amblyopia, although the abuse of alcohol and tobacco was denied He had typical scotomata for all colors on both sides, death from pulmonary tuberculosis

Eight of these fourteen patients had demonstrable central amblyopia and central scotomas Of the remaining six, in one, although the case is described as an intoxication-amblyopia, the scotoma is not mentioned, and in others either it was not present or the patient's general condition was such that it was not possible to demonstrate it In all of these, however, the ophthalmoscopic appearances were those usually found with central scotoma

Alcohol was probably the cause of the optic nerve lesion in seven, alcohol and tobacco combined in two, diabetes and tobacco combined in one, tabes dorsalis associated with the abuse of tobacco and alcohol in one, tobacco was the probable cause in one, although its abuse was denied and the patient died of tuberculosis, in another, although the influence of tobacco and alcohol could not be proved, the clinical symptoms indicated intoxication-amblyopia, and in one the central scotoma existed without such influence Even in those cases in which alcohol seemed to be the most potent agent, the effect of tobacco could not be entirely excluded Finally, it will be noted that all of the patients suffered from various types of widespread disease Therefore we are not actually in possession of the results of an autopsy on a perfectly pure case of intoxication-amblyopia My endeavors to establish toxic amaurosis in monkeys and dogs were failures, probably because the drug was not continued for a sufficiently long time

When, however, a definite set of clinical symptoms are taken into consideration, with the results of autopsies thus far recorded, we have reason to believe that the pathologic process which determines an intoxication-amblyopia is situated in the optic nerve, and especially in that portion which is known as the papillo-macular bundle

[10] Recently Nuel (British Medical Journal Sept 12 1896 p 629) insists that central toxic scotoma is not primarily a neuritis of the macular bundle but a disease of the macula lutea causing degeneration of its cells and that the optic nerve changes are secondary to the destruction of the nerve cells of the macula Some experimental confirmation of this view may be found in the research of Usher and Dean (Ophthalmic Review July 1896) who have observed macular fiber degeneration follow experimentally produced retinal lesions Clinically we know that atrophy of the tissue of the macula lutea e g in atrophic central retino choroiditis will cause ophthalmoscopic quadrant atrophy of the disc As long ago as 1874 Schoen and later Baer and Treitel advocated the retinal origin of central scotoma, believing that it indicated a functional weakness of the center of the retina, due to toxic agents

[14] Loc cit

These *clinical symptoms* are as follows Diminution of sight, associated with fogginess in center of field of vision, unimproved by glasses, reduced acuity of vision, which varies from counting fingers to 20–30 (according to Groenouw from 5–200 to 20–30), pallor of the temporal half of the disc, or of a quadrant-shaped portion of the papilla, normal peripheral boundaries of the field of vision symmetrical central color scotomas, especially for red and green, usually oval in shape, stretching from the fixing point to the blind spot and rarely passing much to the nasal side of the former, defective light-sense (Berry, Abney), but according to R Wallace Henry, normal light-perceptive power

Of these symptoms the most important is the *central scotoma,*[15] and did time permit, it would be profitable to study in detail its development, enlargement and retrogression, which, as Groenouw remarks, represent a characteristic picture—a picture, moreover, according to Wildbrand, which is analogous to that produced by retro-bulbar axial neuritis, except that in the latter the defect is absolute

The average size of this scotoma, according to Sachs's measurements of fifty-three fields is out 18 degrees, in 5 degrees, up 7 degrees, down 6 degrees My own average measurements are out 18 degrees, in 3 degrees, up 7 degrees, down 6 degrees It is thus, as we see, an oval with its pointed end toward the blind spot and its blunt end toward the fixing spot, to the nasal side of which it passes only slightly

This scotoma represents a red-green-blind area, and commonly the extent of green blindness is greater than that of red, which in its turn may be surrounded by an area of imperfect color-sense The "culmination spot," or "nuclear spot," to use the phraseology of Sachs, of the scotoma "lies horizontally from 1 degree to 8 degrees in a lateral direction from the fixation point, its breadth, vertically, being mostly below the horizontal line" Sometimes, however, as we know from Groenouw's observations, the beginning is a small, easily overlooked scotoma exactly over the fixing point

When the typical egg-shaped scotoma is developed which, according to Groenouw, results from the union of the scotoma from the fixing spot with a supplemental scotoma around the blind spot, the process may cease, or there may be a stage of progression, characterized by an increase in the size of the color defect, usually above, until it meets the limit of the red field, *i e*, the scotoma has "broken through" If this goes on the patient may eventually resemble a congenitally color-blind person In severe cases scotomas for blue and yellow form in similar manner to the red-green scotomas especially, according to Baas,[16] in the period of "breaking through" Finally, small absolute defects may be found, particularly at the "nuclear spot," but also elsewhere, and in neglected cases, or in those not typically toxic, the scotoma becomes absolute

Instead of the typical egg-shaped or oval scotoma, the visual defect may pass up and out or down and out Occasionally a circular scotoma surrounding the fixing point has been described, for example, by Nettleship, Nelson and by myself

In cases supposed to be more purely alcoholic in origin, either in addition to the relative scotoma for red and green, or instead of it there may be, according to Uhthoff, complete or partial peripheral defects for these colors In rare instances a small central scotoma for blue appears, and exceptionally there are absolute scotomata surrounded by a blue-blind zone and more peripherally by a red-green-blind region, the periphery for white being normal According to R Wallace Henry,[17] if the visual field is full, nicotin is the determining cause of the amblyopia, if spirally contracted (a "retinal exhaustion" field), alcohol is the determining factor A differential diagnosis between alcohol and tobacco cases, based upon the "pericentral" or "paracentral" position of the scotoma, as originally suggested by Hirschberg, has been shown to be inaccurate

The various drugs and toxic substances which may be responsible for the clinical symptoms which have just been detailed are tobacco, alcohol, either singly or combined, stramonium, cannabis indica, chloroform, opium, cocain (?), bisulphid of carbon, nitro benzol, arsenic, lead, iodoform, the toxin of diabetes and probably, according to Baas, ioduret and thiuret, two modern antiseptic preparations

Clinically, at least, tobacco is *facile princeps* of these deleterious agents, although its effect on the system is usually combined with that of alcohol, the relation of alcohol being not only that of an additional poison, but also that of a substance which predisposes the system to the influence of tobacco by depressing nutrition and creating chronic gastritis, because there seems little doubt that the influence of the tobacco is much more potent if the patient is the subject of chronic gastric catarrh Indeed, Horner at one time believed that this was the sole influence of tobacco It did not, according to this author, produce the amblyopia, but it created the nutritive disturbances which in their turn were responsible for the visual defects

Sachs seeks to explain the action of tobacco in relation to toxic amblyopia in the presence of stomachic catarrh by assuming "that certain complex chemic combinations occur chiefly in the stomach and probably result from the transformation of the normal gastric juices into acids of the fatty type, whose compounds with nicotin are either more readily absorbed, or are with greater difficulty eliminated from the system than the simple tobacco bases" There is no doubt that nicotin is neither alone nor chiefly responsible for the deleterious effects of tobacco upon the visual apparatus, or, indeed, upon the nervous centers generally It is not unlikely that the nicotin of tobacco smoke is almost completely, if not entirely, decomposed during the combustion of the tobacco, and we must probably look to other compounds, pyridin, collodin, carbonic acid, etc, for influences which have usually been solely attributed to nicotin

The action of alcohol on the optic nerve is no doubt analogous to its influence on nervous tissue generally and on individual organs, for example, the liver and the kidneys, indeed, we have seen that the pathologic processes are similar

In the absence of microscopic investigations we assume by clinical symptoms that the other drugs in this list produce a papillo-macular scotoma in like manner. Four of them, lead, arsenic, nitro-benzol and bisulphid of carbon, find their chief subjects among workmen who are engaged in handling these substances. Three of them, cannabis indica, chloroform and opium, to which list perhaps stramonium, arsenic and probably cocain should be added, are potent among drug-drunkards. Three of them manifest their deleterious influences chiefly after absorption through the skin, namely, iodoform, ioduret and thiuret, although iodoform may enter the system by stomachic absorption.

---

[15] Sachs objects to the designation 'paracentral' or 'central' as conveying a false impression and contends with justice for the term papillo macular scotoma

[16] Das Gesichtfeld Stuttgart 1896, p 164

[1] Ophthalmic Review, xv, No 172 1896

With the exception of cannabis indica, stramonium, opium, cocain (?), iodoform and perhaps some of the cases of bisulphid of carbon and nitro-benzol poisoning, the clinical symptoms of the visual defects of this list of substances are more analogous to those of an axial neuritis than of pure intoxication-amblyopia. This is notably the case with lead.

The prognosis of toxic amblyopia is favorable when only a color scotoma exists and recovery is probable as Groenouw points out, even when small absolute defects are present. In the earlier stages, especially of the tobacco cases, the indications are rather of vascular disturbance than of true neuritis, or perhaps, as Sachs points out, the alterations do not at first affect the nerve fibers, but merely the areolar septa. The nervous tissue is temporarily injured, and cure is therefore possible. When optic nerve atrophy ensues, we may assume a real retro-bulbar neuritis. Nevertheless there appears to be a type of optic nerve atrophy in which, as Lawford[15] has said, although tobacco may not be the sole cause, it has some share in originating or aggravating the changes in the optic nerve, or, again, as Browne[16] has suggested, "there are cases of retro-bulbar neuritis which begin with the ordinary clinical symptoms of intoxication-amblyopia, but which do not tend to recovery, the progression of the central scotoma indicating that atrophy of the papillo-macular bundle takes place. What is the rôle played by tobacco and the other agents thus far mentioned in these cases has not been positively determined. No doubt recovery or progression of the visual defect is largely determined by the length of time during which the poisonous substance has maintained its influence as well as by the type of the lesion which it produces as we shall see in the subsequent sections.

2. Progressive and scotomatous atrophy of the optic nerve the result of toxic agents.—The class of

but gradually spreads until the whole nerve is more or less involved and atrophy results. Here a distinct personal proclivity is shown in young persons, members of the same family. Whether there is any ascertainable difference between those cases in which tobacco is the exciting cause and those which occur spontaneously requires investigation." They are probably analogous to the progressive scotomatous atrophy which Jenson[1] has described and which has been regarded by him and by others as a particular form of the development of tabetic atrophy. As has been said before, the relation of toxic substances to this form of optic nerve atrophy is uncertain, but a few cases seem to indicate that they may be at least exciting causes. Of those agents already mentioned, tobacco and alcohol are probably preëminent, lead less certainly. Of the others I am unprepared to speak.

3. General atrophy of the optic nerve the result of toxic agents.—General atrophy of the optic nerve as the result of toxic agents may be divided thus:

1. Those cases in which there is a preceding retro-bulbar neuritis or neuritis papillo-macularis, with central scotoma, and in which the diseased process has spread from the papillo-macular bundle and the axis of the optic nerve until it has involved the peripheral and intermediary fibers. To these cases I have already referred in the two preceding sections, and have pointed out that they probably may be due to tobacco and more certainly to alcohol and lead. To this class I may add bisulphid of carbon and probably arsenic.

2. Those cases in which there is a preëxisting intra-ocular optic neuritis, usually of moderate degree, which is succeeded by an ordinary atrophy, that is, a post-papillitic atrophy. Scotomata are not present in these cases.

The most prominent drugs responsible for this state of affairs are bisulphid of carbon (probably), mercury, iodoform (one case only), and especially lead. Exceptionally subjects of chronic alcoholism exhibit optic neuritis. The same is true of patients who are subjects of the chloral habit. Of all the drugs mentioned the most potent in this relation is lead. For example in sixty-four cases which I have analyzed there were thirteen with optic neuritis, four with neuro-retinitis and seventeen with optic nerve atrophy, while in seventeen cases the patients were stated to be blind without description of the ophthalmoscopic appearance, and no doubt in many of these atrophy or neuthat this visual defect is possible under the influence of chronic mercury, chronic arsenic and especially chronic lead poisoning Referring to the latter I may say that there is certainly an optic nerve atrophy due to the primary effect to lead on the visual apparatus, an atrophy which has been believed by some observers, for example, Parisotti,[23] to be due to changes which lead causes in the nutrient arteries of the optic nerve, changes which we know it may cause in the general retinal circulation

It is probable also that atrophy may occur under the influence of nitrate of silver, in a manner analogous to lead and bromid of potassium It certainly results from the toxic influence of filix mas, although thus far reports of this condition are largely confined to Japanese literature A few cases, however, have appeared in French and German reports, and recently filix mas atrophy has been attributed to filicic acid, Van Aubel[24] believing that this agent acts upon the central nervous system, the spinal cord and the sympathetic, causing dilatation of the pupil and through the vaso-motor nerves contraction of the retinal arteries It is interesting to observe that the blindness comes on acutely, generally after the ingestion of the drug for the purpose of driving out intestinal parasites and that within a few weeks or even shorter time, the arteries shrink and the discs become pallid and atrophic

In this particular the drug may be classed with two others that are able to produce what I may call an acute *optic-nerve atrophy*, namely, quinin and salicylic acid, or to speak more accurately, various preparations of the cinchona bark, and the salicylates The last named drugs, namely, quinin and salicylic acid, produce symptoms so exactly alike that they may be classed together, although the effect of quinin is much more potent than that of salicylic acid

The symptoms are as follows Blindness, complete or incomplete, usually developed with great suddenness and more absolute than in any other recoverable condition (Mellinger and Browne), dilatation of the pupils, absence of the light reflex, imperfect response to accommodative effort, nystagmus, proptosis, occasionally divergent strabismus and increased intraocular tension (Tiffany), anesthesia of the conjunctiva and cornea (Voorhies), extreme pallor of the optic discs and diminution of the retinal vessels simulating the appearances of progressive atrophy, occasionally retinal haze and the cherry-colored spot in the macula, resembling embolism of the central artery of the retina, gradually partial or complete restoration of the central vision, associated at first with complete or partial color blindness, later slow renewal of the color-sense, which may ultimately return, more often permanent diminution of the light-sense and color-sense and contraction of the field of vision, the contraction usually assuming an elliptical shape, very exceptionally permanent blindness (Claiborne)

As we know from the experiments of H Brunner[25] and myself,[26] as well as from those of a recent Italian observer, De Bono,[27] the exact picture of quinin blindness may be repeated in animals, so that there is do doubt as to a selective influence of this drug upon the visual apparatus—an influence, as I have shown in dogs, which extends from the intraocular end of the optic nerve throughout the visual tract as far as this can be traced in the brain But, even now, the mechanism of the blindness is somewhat uncertain Probably it depends upon an influence of the drug on the peripheral circulation of the visual apparatus, which produces at first a pure ischemia, later an endo-vasculitis, and still later, as I have further shown, thrombosis in the vessels and extensive secondary degenerative changes in the optic nerve fibers

Parisotti's idea of the mechanism of primary lead atrophy, to which I have already referred, is similar, namely, that it depends upon changes in the nutrient arteries of the optic nerve Indeed, the analogy does not cease here, because referring to Sachs's observations on intoxication-amblyopia pure and simple, we remember that he suggests, and in fact demonstrates, that vascular changes in the diseased tissues of tobacco-alcohol atrophy, producing proliferating endo-phlebitis and leading to connective tissue obstruction of their vascular lumen, are important factors in the anatomico-pathologic basis of this affection

4 *Atrophy of the optic nerve secondary to retinal and other lesions, in their turn the result of toxic agents* —Thus far we have discussed the visual defects caused by an action of toxic substances falling primarily upon the papillo-macular bundle and ceasing at this point, or spreading and involving other tracts in the nerve, or by an action on the entire optic nerve, preceded or not by an intraocular optic neuritis In a certain number of instances atrophy of the optic nerve is secondary to lesions either in the retina itself, or elsewhere in the body The cases may be divided into

1 Those in which the action of the drug has fallen upon the retinal circulation

Preeminent among substances of this character quinin and salicylic acid should be placed, that is, they should be thus placed if we accept the theories of certain observers in regard to their action, namely, that it is upon the retinal vessels, causing endo-vasculitis and secondary changes My own observations indicate that they affect the vessels of the optic nerve apparatus especially—perhaps, however, an extension of the original retinal lesion

2 Those cases in which the toxic agent has produced tissue change, either in the retina or in the retinal vessels

Preeminent among drugs of this class is phosporus, which early in its toxemia causes retinal hemorrhages and later a fatty degeneration of the retinal tissue itself, which, should the patient live long, would no doubt produce secondary changes in the optic nerve Probably other poisons, chiefly irritant in their effects, have an analogous action, notably the bichlorid and other soluble preparations of mercury The influence of acute poisons upon the retina and the secondary changes in the optic nerve require further investigations If subsequent investigation substantiate the view that toxic scotoma is caused primarily by degeneration in the macula, tobacco and alcohol would find place in this class

3 Those cases in which the primary action of the poison falls upon some organ or tissue of the body, causing a disease which in its turn is responsible for a retinal and secondary optic nerve change

The most notable drug of this class is lead, which, as we know, may produce a nephritis, a neuro-retinitis as the result of this nephritis, and finally optic nerve atrophy Lead, in like manner, may produce an encephalitis, or a meningo-encephalitis and secondary optic nerve changes The effect of alcohol upon the meninges of the brain, causing optic neuritis and secondary atrophy, has already been described Whether the optic neuritis of chloral, mercury, arsenic and nitrate of silver may have a similar origin, I do not know It seems probable that iodoform may cause meningo encephalitis and optic atrophy

OPTIC NERVE ATROPHY OF OBSCURE SPINAL ORIGIN

Read in the Section on Ophthalmology, at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5-8 1896

BY DUNBAR ROY, A B , M D
PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY IN SOUTHERN MEDICAL COLLEGE OCULIST TO SOUTHERN R R HOME FOR THE FRIENDLESS
ATLANTA, GA

The important relationship existing between the optic nerve and other portions of the central nervous system, especially the spinal cord, has long been recognized by both neurologist and ophthalmologist In fact, most clinical observers will readily agree with Gowers,[1] in considering the optic nerve in its development, nothing more than an extension of the central nervous system and anatomically of the same structure as the brain and spinal cord The pathologic relationship between the diseases of the optic nerve and cerebrum are not so difficult of demonstration, but when we consider this same relationship in diseases of the spinal cord, pathologists must as yet acknowledge their inability to discover any direct anatomic connection

The portion of the subject allotted to me is not the discussion of diseases in general of the optic nerve, which are dependent upon, or associated with pathologic conditions of the spinal cord, but the consideration of those cases of optic nerve atrophy, only, which bear this relationship to well recognized lesions of the spinal cord I say "associated with" because no casual dependence has as yet been anatomically demonstrated, but because we observe clinically an atrophy of the optic nerve, and at the same time certain pathologic lesions of the spinal cord we are in the habit of trying to trace some casual relationship Clinical facts can not always be explained by theoretical reasoning or absolute anatomic demonstration, yet we learn to class them as truths, because of their frequent occurrence under almost identical conditions

Most writers divide atrophy of the optic nerve into two classes *a*, primary, *b*, secondary In primary atrophy disturbance of vision is usually present with the beginning of the atrophic process, both increasing together, while in the secondary form there may be a disturbance of vision long before there are any appearances of degeneration or atrophy in the nerve substance itself, but it is doubtful whether the final appearance of these disks can differentiate the two classes Primary atrophy occurs most frequently without any discernible cause, yet sometimes is distinctly traceable to heredity In this form of atrophy previous inflammatory signs never exist

By secondary atrophy is meant those cases in which the morbid condition may be traced to distinct causes as for instance those following intrabulbar neuritis or choroiditis, ultro-bulbar neuritis, traumatism and direct extension of the process from the cerebrum itself

Atrophy of the optic nerve occurring in this connection with simultaneous lesions of the spinal cord presents the clearest example of the so-called primary atrophy

To aid us more clearly in this discussion, I propose to treat the subject under the following three captions

1 Optic atrophy associated with lesions of the spinal cord and bulb, as

a *Meningitis*—Optic nerve atrophies resulting from or following an acute inflammation (meningitis) of the meninges or nerve substance proper (myelitis) of the spinal cord and medulla, must be classed as consecutive, instead of primary Such could only occur as the extension of the inflammation from the spinal cord to like structures in the brain, with a simultaneous involvement of the optic nerve Cases of this kind are exceedingly rare

Gowers[2] mentions a case of the optic atrophy following an attack of sporadic cerebro-spinal meningitis A boy was brought to him, who after a thorough drenching had suffered from severe headache, delirium, fever and stiff neck Ten days later he became blind After the blindness, the other symptoms disappeared, and when examined by Gowers there was present only a small degree of light perception in one eye The papillæ showed the picture of consecutive atrophy, the centers being filled with new connective tissue, the vessels were narrowed, and the choroid in the neighborhood of the papillæ showed marked changes This author has mentioned two other cases of the optic atrophy following myelitis of the cord which were reported by Clifford-Allbut In one there was a slight optic neuritis, with indistinct borders of the papillæ, resulting finally in a gray atrophy, and in the second a partial gray atrophy the cause of which being, probably, a chronic myelitis of the cord of the dorsal region

A very interesting case has been reported by Dreschfeld[3] He had under his care a man 24 years old, who with the simultaneous development of double optic neuritis, which led to complete atrophy, developed symptoms of acute myelitis, from which he died in one month The autopsy showed acute disseminated inflammation in the dorsal and lumbar region of the spinal cord The brain appeared perfectly normal

b *Locomotor ataxia*—The association of optic nerve atropy with tabes dorsalis has been recognized as an early symptom of this latter disease for many years A new impetus was given to the study of this associated pathologic condition by Smeichler,[4] who in 1893, published the result of his studies in a large number of cases found in Professor Alt's clinic at Vienna, and called attention to optic nerve atrophy as an initial symptom of beginning tabes Such cases of optic nerve atrophy occurring in this connection must be classed as primary, for the ocular symptoms, as a rule, always precede any final manifestation of the disease, and there is never any history or signs of a previous neuritis In fact, some observers, especially Charcot, have held that all cases of primary optic nerve atrophy are associated with tabes of the cord, and that, although the spinal symptoms may not be present at the time, they will appear at some period during the patient's life

On the other hand, Uhthoff,[5] with whom Gowers agrees, holds that in only half of such cases [illegible] there ever any affection of the [illegible] A[illegible] to

Galezwoski[6] about two-thirds of all optic nerve atrophies are tabetic, while Pelteshon[7] found still higher percentage, namely seventy-eight out of ninety-eight cases

The converse of this question, namely, in what per cent of cases of tabes is optic nerve atrophy present, is not so easily answered Gowers[8] remarks that we are very near the truth when we say that out of every six cases of tabes, one will suffer from optic atrophy Among seventy cases which he observed in succession, of persons suffering from locomotor ataxy, only nine had optic nerve atrophy Voights[9] among fifty-two cases found atrophy nine times, while Erb[10] among fifty-six cases, found atrophy seven times

From the study of this subject, it will be seen that nearly all cases of primary atrophy of the optic nerve are associated with tabes of the spinal cord and that this association with other sclerotic processes in the cord is very insignificant in comparison That the one is dependent upon the other is not probable, but my own observation leads me to believe, that since the two processes are degenerative in character, it is simply fortuitous as to which part of the nervous system is first attacked

Gunn[11] has very thoroughly studied these points and very properly raises the question as to the existence of independent changes in both the spinal cord and the optic nerve

As Gower says, "the pathologic relationship between optic nerve atrophy and individual lesions of the spinal cord is yet dark The fact that the atrophy can be very far advanced in tabes when the changes in the cord itself are, as yet, in the very first stages makes it probable that the changes in the optic nerve are associated with, rather than a result of the spinal cord lesions "

That there is a close relationship, all must admit, but no postmortems have shown any direct anatomic connection

Knies[12] says that the process in the optic nerve begins as a disseminated one, and that the atrophy extends in an ascending or descending direction The middle fibers of the nerve remain longest intact, and we may, therefore, infer an action starting from the periphery This may take place most readily at the place where the nerve passes through the unyielding optic foramen

The gray atrophy is also noticeable in the chiasm, tractus, and as far as the primary optic ganglia, but there is no direct connection with the degeneration of the spinal cord

Pathologic anatomy has not demonstrated the truth of the statement made by Landois and Stirling[13] that "the discovery of the partial origin of the optic nerve from the spinal cord, explains the occurrence of the amblyopia (with partial atrophy of the optic nerve) in disease of the spinal cord and especially in tabes " The only connection between the eye and spinal cord is found in the sympathetic nerves, which come from the cilio-spinal center in the cervical region of the cord, and whose connection with the iris is such that their stimulation will produce a dilation of the pupil But this connection is anatomically so slight that it would be a matter of impossibility to imagine a process reaching the optic nerve from the spinal cord by means of this route A most excellent summary of the views at present held were given by Gowers,[14] in opening a discussion upon "Eye Symptoms in Diseases of the Spinal Cord before the Ophthalmological Society of the United Kingdom '

This writer holds that optic nerve atrophy and internal ocular paralysis must be regarded as associations, not an effect of spinal lesions Because 1 Diseases of any nature may exist in any part of the spinal cord without occurrence of ocular symptoms, if we except rare paralysis of the dilators of the pupil in disease of the sympathetic tract in the cervical region 2 The ocular symptoms which may be absent when the cord disease is advanced, may exist in an extreme degree, when such disease is in a very early stage 3 With the single exception of the sympathetic symptoms just mentioned we know of no anatomic mechanism by which the spinal cord can produce the ocular symptoms

What is true of tabes is essentially true of other sclerosing processes in the spinal cord It matters not whether the atrophic or sclerotic process commences first in the optic nerve or spinal cord, this one fact remains clear that the pathologic processes show some similarity in character These associated ocular symptoms are the results always of degenerative processes, and their presence shows that the cord disease is essentially degenerative in its nature This is made evident in the slow progressive character of the spinal symptoms

The researches of Pierret, confirmed in part by Dejerine and anticipated partly by Westphal, have enlarged and altered our conception in regard to tabes dorsalis, which, in some measure, throws a ray of light upon the association of this malady with optic nerve atrophy

Pierret has shown that degeneration in the optic nerve is not the only peripheral lesion and that the same in the cord is not the only central change in the disease Often there is independent degeneration in the cutaneous nerves, commencing in their extremities, to which the optic nerve change is analogous There may be degeneration at the central termination of the optic as well as other cranial nerves, analogous to that in the posterior columns of the cord He terms it "wide sensory neurosis "

What has been said applies not only to tabes in particular, but to all morbid conditions of the spinal cord presenting degenerative changes in the nerve structure

Ocular symptoms, especially optic nerve atrophy, have long been a diagnostic sign in spinal cord lesions, especially tabes So frequently is this association present that clinicians are in the habit of associating all primary atrophies of the optic nerve with similar degenerative processes of the cord From what has been said it is evidently improper to speak of optic nerve atrophy of spinal origin, unless we mean its origin is from the same source, as is the associated lesions in the spinal cord

The symptoms of optic nerve atrophy associated with tabetic changes in the cord are said to be very characteristic, which is true when they all exist, but there are many cases of atrophy where only two or even one diagnostic sign is present, as, for instance, in those cases of slow development of the ataxic symptoms, and in such cases one can not positively recognize such associated pathologic changes

The appearance of the disc in the optic atrophy occurring in connection with tabes, is said always to be of a characteristic gray color instead of white, and this discoloration of the disc has been frequently commented upon by various writers Especially is the color gray, or pearly white by the indirect ophthalmoscopic picture, while by the direct it is gray or mottled, presenting sometimes according to Gowers, "a peculiar gelatinous opacity." Yet he who would make a diagnosis solely through the color characteristics of the disc will often err, for I have seen true cases of tabetic atrophy, where the appearances much more resembled the whitish than a grayish tint, and for that reason I fully agree with Dr. Young, who says that there is always a possibility of inaccuracy since expert ophthalmologists may honestly differ in the question of definite color. Furthermore, Gowers has called attention to the fact that gray atrophies occur under other pathologic conditions, as, for instance, in consequence of the post orbital pressure upon nerves already atrophic from other causes than tabes.

The histo-pathologic changes in this form of tabetic atrophy have been thoroughly studied by Uhthoff, Gowers and Leber. According to the latter author, the microscopic appearances in the nerve show an increase in the interstitial fibers and sometimes a formation of transparent cell bodies around the vessels and at the same time atrophy of the nerve fibers. Another point which is noted in this form of atrophy is the normal caliber of the blood vessels especially the arteries, which in other forms of white atrophies are usually smaller in size. This, according to Knies, is due to the fact that the original process is located behind the entrance of the central vessels. But, according to my experience, this picture is not universally present, the conscientious ophthalmologist must be prepared for deviations on this point. The disturbance of vision which occurs in connection with tabetic atrophy, for both form and color, is another important symptom. It has been especially noted that the ophthalmoscopic picture is no criterion for estimating this disturbance of sight. Cases are sometimes seen where the disc is atrophic throughout and yet there is but a slight diminution in the vision, while even in the majority of cases atrophy appears before there is any disturbance of this function whatever.

Yet another symptom, perhaps the first, is the contraction of the field of vision for both color and form, this contraction following in this order, green, red and white, until there is a total achromatopsia. The field of vision for both form and color is a concentrically narrowing one, progressing gradually until there is a very narrowed, central circle remaining, corresponding perhaps to merely the point of fixation and this gradual narrowing may continue for years before there is total loss of vision, and before the patient is aware of the diminution of sight. This loss of vision is very gradual and slow, and such cases as the one reported by Hirschberg,[1] where vision was almost entirely lost in eight weeks, are extremely rare. Knies[16] says that, prognostically, the color disorder is important, because those cases in which the color boundaries are very much narrower than those for white belong to the rapidly progressive cases.

A central scotoma in this form of spinal atrophy is extremely rare and when it does occur should, according to certain writers[1] excite a suspicion of other spinal lesion than tabes. The "Argyll-Robertson pupil," or one which responds to accommodation but not to light, has to me proven of more value in substantiating the correct diagnosis of this disease than all others, and this symptom will exist even in the very latest stages.

Many writers say that a contraction of the pupil is an early symptom of tabetic atrophy, calling it a "spinal myosis," but my observation leads me to consider this sign as exceedingly transitory, finding as a rule, mydriasis rather than the opposite. A much more constant symptom is the inequality in size between the two pupils and which is far more pathognomonic than a myotic condition. One question in connection with this subject is whether a primary gray atrophy will always be followed later by the ataxic symptoms of tabes, as is held by some writers. This is a question most difficult to answer, because of the time which may elapse between the appearance of the optic atrophy and the tabetic symptoms. In the majority of cases it is a matter of great difficulty to keep patients under close observation for long periods of time, hence it is that a statistic report is difficult to obtain.

Kahler has reported a case where atrophy existed seven years, Charcot, a case where it existed ten years, and Gowers one of fifteen and twenty years before there was any marked tabetic symptoms. I deem it unnecessary to report here the histories of cases of this affection, because cases of optic nerve atrophy in association with tabes dorsalis are by no means infrequent, and none of those which have come under my observation presented any symptoms which are not common to all such cases. The prognosis in such cases of optic nerve atrophy is bad and we have yet to find the remedy which will benefit them.

c. *Multiple sclerosis.*—In this affection it is a matter of impossibility to consider the pathologic process as confined exclusively to the spinal cord, for it is well known that the sclerotic process is liable at the same time to involve any portion of the cerebro spinal system, and rarely is there a limitation to one particular part. Hence, when optic nerve atrophy does occur simultaneously with insular sclerosis in the spinal cord the same sclerotic process will be found also in the brain substance. My colleagues will no doubt call your attention to this point when discussing the brain lesions, for with the majority of writers multiple sclerosis is more frequently spoken of as brain than as spinal lesion.

The observations of Buzzard[18] do not agree with the majority of writers, when he says that atrophy of the optic nerve is most frequently associated with insular or disseminated sclerosis, next frequently in connection with fasciculated sclerosis of the posterior columns (in tabes and general paralysis of the insane), and least often with fasciculated sclerosis of the lateral columns.

According to Knies, pronounced atrophy of the optic nerve in this affection is rare, about 3 per cent., incomplete or partial atrophy about 19 per cent.

Gowers says that atrophy occurring in this connection is very similar to that occurring with tabes, and until the ataxic symptoms appear the diagnosis is somewhat difficult. In pure insular sclerosis of the spinal cord he has never seen optic nerve atrophy occur but three times.

d. *Lateral sclerosis.*—This pathologic condition constitutes the last of the chronic sclerotic conditions of the spinal cord with which atrophy of the optic nerve is sometimes found associated and likewise the most infrequent.

Gowers has never seen this associated symptom but twice in all his vast experience. Such would naturally be expected, since many cases diagnosed as lateral sclerosis have been found, postmortem, to be due to some other lesions, hence the nervous organic lesion must be accurately diagnosed first before we can associate it with optic nerve atrophy The same writer above referred to has reported a case of combined sclerosis of the posterior and lateral columns, with gray atrophy of the optic nerve and bilateral oval central scotoma especially for red and green This latter symptom is held by some, as before mentioned, to be a differential sign between optic atrophy associated with tabes and other pathologic lesions of the cord

e *Injuries of the spinal cord* —As we progress still further into the pathologic changes of the cord with which optic nerve atrophy is associated, we are confronted at every turn by a yet wider obscurity in connecting the two lesions

There was certainly no necessity for the use of the word "obscure" in connection with this subject under discussion to-day, for as soon as one begins to study the literature of the subject and his own personal experience, he is confronted on all sides by nothing but obscurity There have been a few cases of optic nerve atrophy reported, which occurred at the same time or some time after an injury to the spinal cord, hence it was natural to consider the atrophy somewhat in the light of a *propter hoc* Ever since Erichsen gave to the medical world, and now the special property of the legal profession, his brochure upon "Spinal Concussion," this subject of spinal injury or "railway spine" has been a fruitful field for a large amount of medico legal harangue

Injuries may occur to the spinal cord without any discoverable injury to the vertebral column (concussion), yet when this latter is involved we can much more readily discover the relationship between the seat of injury and the spinal symptoms In this, as in all pathologic conditions of the cord, if optic nerve atrophy should arise it must be looked upon simply as an accidental association, not in any causal relation, since, as yet, no anatomic connection has been found to exist

Wharton Jones states that affections of the optic nerve are frequent after injuries of the spinal cord, but fails to add that atrophy as one of these is exceedingly rare What changes do occur, especially in cases of concussion, are referable to changes produced in the sympathetic system, which presides over the vaso-motor functions of the body

Fowler[19] has reported the case of a man who was thrown from a caisson during the war and was run over, the wheel passing over the lower portion of the dorsal region The lower extremities were paralyzed for a few months His back rendered weak, he perspires freely and his face flushes easily, no suspicion of syphilis Sight failed gradually from optic atrophy of both eyes and vision was finally lost altogther

Caries of the vertebral column is but another form of injury when it involves the cord Abadie[20] has published a supposed case of caries of the vertebral column at the base of the skull, which was accompanied by atrophy of the optic nerve together with a meningitis So far, I have been unable to discover in literature any trustworthy cases of optic atrophy where such a casual relationship could be found, as injury to the spinal cord

f *Trophoneuroses* —Under this head medical literature does not afford us many cases of associated optic atrophy, and I have been unable to find but one authentically published case This was "A Case of Acromegaly, with Atrophy of both Optic Nerves" reported by Dr George Carvell[21]

Male, aged 52, carpenter Father died of old age and debility, while mother died of pulmonary disease None of patient's relatives had similar conditions to his own

History Up to twenty years ago patient had enjoyed good health, and between the ages of 20 and 30 was able to wear No 8 glove When about 30 years old he began to grow stout and suffered from general weakness He still continued to work until his sight began to fail Five years ago he was unable to read a newspaper, and from that time has become worse During the last few years has suffered from shooting pains in the arms and legs, especially in hip, knee and ankle joints, complains of coryza *Present condition* Is of medium height, corpulent, and clumsy in movements, pallor of face and lips, nose is large, malar bones prominent, occipital tuberosity and lower jaws are unusually developed, the latter protruding in front of upper jaw, internal organs healthy, urine, orange color, specific gravity 1030, urates in great abundance, no sugar or albumin Eyes pupils of equal size and react to light and accommodation, right eye vision=6-60, left eye vision=fingers at one meter, no improvement with glasses Ophthalmoscope=marked optic atrophy in both eyes, discs milky, edges sharp and defined, fields laterally diminished, especially in right eye Color Distinguishes blue and green, calls red and yellow buff

2 Optic nerve atrophy occurring in connection with diseases of the peripheral nerves —According to Knies, diseases of the peripheral nerves rarely affect the eye unless they belong to that organ, or are adjacent to it In multiple neuritis an optic neuritis sometimes occurs, but no cases of optic atrophy have been reported where a causal dependence could be found In the medulla, cases have been reported where there occurred optic atrophy at the same time or following certain affections of the peripheral nerves, which have their nuclear origin from this source In chronic bulbar paralysis, changes in the optic nerve, while sometimes occurring, are very rare Galezwoski has observed and reported a case of one sided optic atrophy which occurred in connection with a chronic progressive paralysis of the bulbar nerves Robin cites a very interesting case from Von Dianaux, where a rapid atrophy of both optic nerves appeared in a man 76 years old, who was suffering from a deep affliction It was also accompanied by a paralysis of the sixth nerve The vision was entirely lost in two months, yet, when he was again seen some time later, the vision had increased even to one-tenth

A full history of double optic atrophy in connection with bulbar paralysis is reported by Drs J W Barrett and P S Webster of Victoria, Australia

E C, aged 30 Symptoms began three years ago with drooping of the left lid and turning outward of the eyeball When first seen six months ago the following conditions were present Right eye, pupil 6 millimeters, does not react to either light or accommodation, no external ocular paralysis Vision=5-60 Emmetropic, optic disc very pale from primary atrophy Left eye, pupil 7 millimeters, no action to light or accommodation, paralysis of internal and inferior rectus, weakness of superior rectus Vision=fingers at two feet, contraction and loss of color vision, at present fields are much smaller Right eye vision=5-60, left eye vision=light perception, paresis extended to internal rectus and superior rectus in right eye and has increased in the muscles of the left supplied by the third nerve

Patient's general health good and he has no other spinal symptoms At one time he suffered from headaches and has had a little rheumatism Seventeen years ago had a chancre and was treated two months No secondary symptoms

Diagnosis —Atrophy of optic nerve and independent specific nuclear affection of the nerves implicated

Through the kindness of Dr H V Würdemann I am enabled to report another very interesting case

T G, aged 38, hack driver Presented himself on account of a nervous trouble in both eyes

Examination —Right eye vision=5-12, left eye vision=5-12, total paralysis of third nerves, except the branch going to levator palpebræ sup The perimeter showed lateral (homonymous) hemianopsia for form and for white, red and blue There was total achromatopsia for green By ophthalmoscopic examination the optic discs were white and atrophic, especially the macula fibers Syptoms of multiple sclerosis were present also in other organs

Leaving now those pathologic conditions of the spinal cord and medulla, where distinct anatomic changes could be discovered we come to the third division of our subject and that portion enveloped still farther in the domain of obscurity

3 Optic atrophy associated with functional neuropsychoses such as hysteria, chorea, etc —It may be questionable whether the discussion of this last division belongs properly to the domain of the spinal cord, but since the symptoms of those diseases classed under the head of "neuropsychoses" manifest themselves most prominently in those portions of the body whose activity are dependent upon their relationship to certain nerve centers in the spinal cord, it seems but proper that the spinal cord should take a more prominent position than any other portion of the cerebro-spinal system

Most of the functional neuroses are still enveloped in obscurity, and since the etiology of the diseases themselves are still a matter of dispute, it is but natural to suppose that any association of optic nerve atrophy with the same affections should be still further beyond the reach of even theoretic reasoning

a Hysteria —In this disease we all know of its multiform symptoms and of the appearance occasionally of various ocular manifestations I have been unable to find any authentic case of optic atrophy whereby a relationship of the two diseases could be established, and Gowers says that in one or two cases of hysteria optic atrophy has been observed, but that its presence was probably purely accidental, or there existed at the same time some organic disease, as disseminated cerebro spinal sclerosis In fact, in all functional nervous troubles any appearance of optic atrophy can not be regarded as anything but accidental and not causal

Weir Mitchell,[24] in narrating a case of tabes in a child, calls attention to the fact that in hysteric ataxy, in contradistinction to the congenital forms, both optic discs are gray, the arteries too small, the veins and pupils normal, the red and blue fields typically reversed and fields for form contracted

Buzzard[18] calls attention to the fact that contracted normal fields should make us hesitate in diagnosing "hysteria," even though there are no appearances of atrophy of the optic nerve, for often in such cases a change in the nerve, which ultimately ends in atrophy, will subsequently show itself

On the other hand, Leber[23] has found objective changes in the optic nerve in amblyopia with concentric narrowing of the field, which, according to Charcot, is characteristic of hysteria These changes were found, by postmortem and microscope, to consist in an occasional atrophic process in some bundles of the optic nerve fibers in front of the chiasm, indicating that the process was peripheral, yet, so far, no case has been reported where a complete atrophy of the optic nerve was present In Leber's case the optic nerve appeared perfectly normal to the naked eye

b Chorea —The pathology of this disease is still a matter of dispute Various anatomic lesions have been found associated with this disease, but its nature is still a matter of dispute According to Germain Sée and many others, it has a rheumatic basis, while Joffroy holds it to be in the cerebro spinal system and is unconnected with rheumatism The connection between chorea and heart disease has been frequently noted, hence some consider those cases of optic nerve atrophy which are found associated with chorea to be dependent upon emboli of the vessels of the optic nerve

A few cases of optic nerve atrophy occurring in persons at the same time or previously suffering with chorea have been reported From one of the assistants in the neurologic department of the Manhattan Eye and Ear Hospital I have ascertained that the percentage of optic atrophies in true cases of chorea is about 1 in 250

Such cases as have been reported have all been due to an embolus in the central artery of the retina, hence must be traced back to some probable organic disease of the heart An interesting case is reported by William George Sym[26]

B M , boy, aged 17, came to Royal Infirmary complaining of loss of sight in right eye History Had perfect vision up to ten years ago, at that age he had an attack of chorea He made a good recovery from this until one morning, when he felt a sudden mist come over the right eye At that time he was walking, never received any blow or injury near the eye nothing unusual in family history, neither parent is rheumatic, but one brother was said to have had articular rheumatism Examination Left eye vision=20-20, right eye vision=0, no perception of light, right eye does not converge on fixing a near object, pupil does not contract to light, tension normal Examination by ophthalmoscope Right eye presented absolute atrophy of optic nerve, disc being dead white, blood vessels extremely small, no traces of hemorrhage and exudation, and disc, in which cupping of optic atrophy was well marked, was normally regular in outlines, macula normal, choroid coat apparently normal, no staphlyoma Left eye normal in appearance, evidence of stenosis in mitral valve

Conclusion Atrophy of right eye due to embolus plugging arteria centralis retinæ of that side and thus cutting off blood supply to retina, this having occurred during the attack of chorea at the time he felt the mist over his eye

Atrophy following neuritis almost invariably affects both eyes, though one nerve may be more advanced than the other Here we have atrophy of one, associated with a normal condition of the other In children, bilateral simple atrophy is rare and so is neuritis, unless dependent upon some gross brain lesion Dr Sym mentions the fact of Gowers having said that there is on record only two cases of embolism of the arteria centralis retinæ occurring in consequence of chorea However, Argyll-Robertson has mentioned a similar case occurring in a young lady, so that I am confident that there probably exists other cases which have never been reported In the study of any subject one must be content with such published reports as can be found in the literature, in hopes that by the publication of these and his own personal experience, others may be brought to light which have been resting in obscurity

In idiopathic epilepsy, where many of the symptoms of this disease show some involvement of the spinal cord I have been unable to find any reported cases of associated optic nerve atrophy, although other changes, such as hyperemia, anemia, narrowing of the blood vessels, edema, etc , of the optic disc have been noted by various observers In general paralsis of the insane, which involves the whole cerebro spinal system, changes in the optic nerve of various kinds have been noted, [illegible] a [illegible] them atrophy Bullard,[18] in 400 [illegible] tion, found complete blindness only three times This was due to a gray atrophy of the optic nerve, similar in all respects to that found in tabes, and hence the causative relation bears the marks here as in tabes In forty-seven cases Jehn[27] found marked atrophy seven times, in three the atrophy was double, while in four it was only on one side Writers also hold that a slight degree of atrophy with amblyopia is still less frequently observed than complete atrophy

Galezwoski,[30] in forty-eight cases, has only observed beginning atrophy once, while Boy has observed it four times among eighty cases, which were thoroughly examined

In this affection, as in tabes, it has been noted that the signs of atrophy may appear some time before the symptoms of general paralysis, and Magnan mentions the fact that he has observed these changes two to four years before the other symptoms appeared

In conclusion would say that it is entirely unnecessary for us, in considering this subject, to qualify the term "obscure," for with all our advancement in pathologic anatomy we are as yet unable to trace the casual relationship of many cases of optic nerve atrophy, and especially is this true when we recognize that this atrophy is in some mysterious way connected with lesions of the spinal cord

Experience and the microscope teach us that certain well defined chronic lesions of the spinal cord are more usually associated with atrophic changes in the optic nerve than certain others, but the *raison d'être* is not yet within the confines of our knowledge Much original investigation can yet be made in trying to extend our knowledge of the subject

The reports of clinic cases, especially those seemingly of spinal origin or relationship, will add much to a more thorough comprehension of the subject, and especially with minute postmortem examinations will be of much substantial value

Loretin versus Iodoform—The comparative results in the treatment of suppurating surfaces are stated by Dr W O Green as follows 1 Loretin is without odor 2 It is slightly more stimulating, and causes more pain perhaps when first applied, but is shortly followed by more permanent analgesic effect 3 It has greater antiseptic properties and on this account, limits and then diminishes more rapidly the local inflammatory condition 4 The process of granulation is more rapid and more perfect 5 The local alterative effect is greater, and therefore the part requires less supplementary treatment in the way of local applications 6 The discharge diminishes more rapidly —*Am Therapist*, September

THE ETIOLOGY AND PROPHYLAXIS OF FUNCTIONAL NERVOUS DISEASES

Read in the Section on Neurology and Medical Jurisprudence at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga May 5-8 1896

BY JOHN PUNTON, M D

Professor of Nervous and Mental Diseases University Medical College and Woman's Medical College Neurologist to All Saints, Kansas City Fort Scott and Memphis, and Missouri Pacific R R Hospitals, etc

KANSAS CITY, MO

In taking a retrospective view of the principal features which characterize the age in which we live, it seems to me none are more conspicuous and striking than the rapid advance of medical science In the many hundred years of its existence no such triumphs are recorded and no such brilliant results achieved as those which belong to the present generation

The principal results of such advance afford us the means of rendering finer discriminations in classification and diagnosis of diseased conditions, and consequent enlargement of medical nomenclature, all of which tend to increase the great mass of specific knowledge relevant to each department In no branch of medicine, perhaps, are the effects of such marvelous changes more visible and potent than those which pertain to the science of neurology

The vast increase of our knowledge of the anatomy and physiology of the nervous system and the application of this to disease has been found to be most useful in the correction of former erroneous inferences Hence a complete revolution has taken place in our knowledge of its pathology, which has also been the means of greatly enlarging the range of its organic diseases at the same time gradually limiting the power and significance of the so-called functional affections

We find that in connection with the study of the histology of the nervous system many other factors were necessarily implicated Among the most important of these was the study of their *etiology* and *prevention*, two of the mightiest forces connected with diseases incident to the progress of modern civilization To trace the intricate change of both structure and function, as well as all the problems connected with the prevention of such obscure neurotic affections is a task which so far has baffled the skill of the brightest intellects of our profession Nevertheless much has been done in not only discovering the cause, but also preventing their occurence by overcoming many of the agencies which contribute toward their production

Nervous diseases are increasing and multiplying at a marvelous rate, and there are physiologists who assert that both the European and American races are deteriorating as their civilization becomes crystallized This is accounted for by the increased demands of modern civilization Recognizing the extreme importance of the subject it is right that we devote special attention to its consideration

It would be impossible for me to refer to the many causes, or the theories which have been offered from time to time, to account for the presence of the varied phenomena associated with the more obscure neurotic affections designated as functional From time immemorial these numerous factors have been recognized to consist of two classes, viz Predisposing, and exciting In the former are included all the conditions pertaining to hereditary neuropathic taints, while the latter embraces all agents which tend to unduly excite the already predisposed, or become the means of creating certain morbid neurotic phenomena

One of the most important facts, which has been clearly demonstrated of late, proves that the entire nervous system in the normal infant and child is constantly undergoing marked changes in both structure and function, and that the former is much more rapid in its development than the latter, and that these are largely influenced by the conditions of heredity and environment, both in retarding as well as developing their normal conditions There is a marked disproportion between motor and sensory cell activity in the child and this can be easily explained on physiologic grounds, but it nevertheless renders the child more vulnerable to certain neuroses, such as convulsions, epilepsy and headache

The highest function of nerve cells is the power of inhibition, and this endowment is the last to be developed in the process of physiologic evolution Cells are capable of generating or storing up nerve energy, beside the power of distributing it For this purpose the cell calls to its aid the various nerve fibers, both afferent and efferent, and their peripheral end organs, hence the whole nervous system becomes subservient to the cell

It is very plain to see that if the generating or discharging functions are not subject to proper control by virtue of their feeble inhibition that nervous instability results, which is highly characteristic of the neurotic diathesis and hence plays a very important rôle in the production of nervous diseases When this abnormal lack of proper nervous adjustment or balance is again augmented by an already existing neurotic predisposition the individual is rendered even more vulnerable to trivial influences

The cell in its normal state has been shown, microscopically to present certain definite characteristics, which when subject to its normal daily activity gradually undergoes definite changes, both in its chemic and morphologic constitution These changes when the normal stimuli are unduly prolonged are even more pronounced The normal results of all cell activity is marked fatigue, but if the activity is unduly prolonged the cell becomes exhausted In the former case the cell still retains the power of its normal reaction during a period of rest, viz, twenty-four hours for every five hours of normal activity (See Rachford on Neuroses of Childhood, p 98) and becomes regenerated, while in the latter case the cell often becomes unable to further respond and is literally in a state of inanition Hence it becomes possible to clinically recognize three classes of cells, viz 1, those which are normal or in a state of rest, 2, those which are more or less fatigued after their normal activity, 3, those which are thoroughly exhausted by over activity

In diseases of the nervous system none of us will have much trouble clinically to recognize conditions representing these changes, for it has been shown by Hodge that the cells suffering from fatigue have a close kinship to neurasthenia, and it is only plausible to conclude that in functional diseases we may at first have similar cellular changes of greater or less degree, which may ultimately give rise to degenerate changes Excessive mental and physical application would therefore seem to be potent factors in the causation of diseases

In a recent article by L H Mettler on "Work and Worry," (New York *Medical Record*, Sept 7, 1895) the writer says in summing up "Work and worry, I therefore take it, are not baneful in themselves, not even when carried to excess, but the monotonous unbroken continuation of the excess is exceedingly injurious"

Professor Erb of Heidelberg (See *Medical Record*, March 16, 1895), in a recent address seemed to regard the feverish activity of the age as a symptom of disease "The over-work, over-crowding, over-stimulation, increased use of tobacco and alcohol, together with excessive railway travel with all its nerve-jarring motion," he thinks all tend to produce a loss of nerve tone, which ultimately results in neurasthenia, which is a refined expression of hysteria and hypochondriasis Commenting on this, the *British Medical Journal* says "While this may be true, there is another side to the picture, in that there is a greater knowledge of the subject, a greater tendency to freedom of exercise, to the freedom from strict conventionality, to the freedom from ailments that come from healthful surroundings, and that worry, not overwork, is the danger of the age, and this danger arises from decreasing and deferred marriage"

Worry is an exceedingly potent factor in the production of nervous diseases and persons suffer far more from the effects of worry of things that never happen than those which actually occur We live in constant anticipation of danger, and this brings with it a continued and prolonged mental state of anxiety The effects of such monotonous routine on the nerve cells is self-evident

The most conspicuous and important cause and that which underlies all the rest in producing and propagating all forms of nervous disease, is the transmission through successive generations of that peculiar bodily condition known as the "neurotic diathesis" This manifests itself by nervous instability and defective innervation of the organic functions, materially influencing the normal development of the nervous system in the offspring and makes itself felt by a constant tendency to degenerative changes in the nerve elements, rendering the subjects of it peculiarly liable to break down under strain that would not affect persons inheriting a different constitution

Jonathan Hutchinson says (See "The Pedigree of Disease") "I would define a diathesis to be any bodily condition, however induced, in virtue of which the individual is through a long period, or usually through the whole life, prone to suffer from some peculiar type of disease" With this definition I fully agree The same author also says 'Some diatheses are inherited, others are acquired Of some the effects are permanent or constant, of others they are transitory or recurrent after intervals of health The term should, however, never be applied to any condition of health which is expected to pass away and leave no trace, for the idea of persistence in some sense is always implied On the other hand, we do not confuse diathesis with dyscrasia, for whilst the latter definitely implies bad health, the former only denotes proclivity and may be used when its subject seems perfectly well" Hence, we learn that the individual diathesis may present itself in every degree from a slight weakness to a very pronounced morbid tendency

The term temperament is also liable to be confounded with diathesis in its more simple manifestation, hence the term temperament is used to designate the "sum total of the physical peculiarities of an individual exclusive of all definite tendencies to disease" Thus says Hutchins[illegible] "To d[illegible]inguish between temperament and [illegible] say " the former is a matter of physiology and the latter of pathology"

Inherited diathesis is more often, than not, entirely latent at the time of birth and is susceptible of aggravation, or in some cases of cure in after-life "Such alternations are not possible in the constitutional peculiarities which we name as temperament"

I have thus dwelt at length on these terms in order to overcome a very common source of useless argument on the part of the profession by failure to comprehend the full significance of certain technic terms

A certain predisposition or tendency to disease is transmitted from parent to child, and often is the only responsible agent for the presence in the offspring of any one of the various neuroses, such as hysteria, chorea, neuralgia, migraine, epilepsy, together with more serious organic spinal and cerebral diseases, including insanity

We do not presume to explain all the intricate details concerned in their genesis, or even the pathologic changes occurring in the tissues and cells, as the laws which govern the transmission of hereditary traits are generally unknown, but the number of inheritable deviations of structure and function are endless

These abnormal conditions of inheritance are often the result of imperfect growth, defective nutrition, incorrect habits, injudicious education and modes of life of the parent, the general effects of which tend to lower the normal standard or health and are marked by having a special injurious influence upon the general development of the nervous system, impairing its functions and exhausting its specific energies The morbid products resulting from such deterioration are readily transmissible from parent to child and furnish the germs which in the offspring establish the neuropathic constitution They are the seeds which may or may not remain latent for years, but if subject to the stimulating processes of the educational period, or the excesses incident to society life they rapidly mature and strengthen until they manifest themselves in some serious form of nervous disease

The same causes which produced the deterioration in the parents are often allowed to have full sway in the child, already predisposed, and then a still greater deterioration is liable to occur Then again, Rachford (See "Neuroses of Childhood") shows conclusively that bacterial products are also important factors in the causation of nervous diseases by their direct poisonous action on the heat centers, thus producing fevers, more especially in children

The same author also states that arterial anemia and venous congestion produce nervous symptoms by their influence on the vaso-motor system of nerves, thereby weakening the inhibitory centers and rendering more excitable the various reflex functions of the medulla and spinal cord

This leads to malnutrition of nerve elements, resultin an impoverished condition of the blood This morbid blood state presents itself in two forms, viz, innutrition and malnutrition, the former representing a quantitative change or reduction in all the nutritive elements of the blood, while the latter implies a qualitative change in the essential constituents of the blood Clinically these conditions are recognized as the various forms of anemia Such conditions are a very common feature of nervous disease, as by far the greater majority of all patients presenting themselves for treatment are found to be below body weight and anemic

Another common source of nervous diseases is reflex irritations of all kinds Recent experiments prove that chronic reflex irritation can produce very marked changes in the nerve cells of the spinal ganglia, and this becomes a potent source of nerve instability, more especially in children and young girls by virtue of their special vulnerability

It is plain that children born of neurotic parentage inherit a weakness, and as growth and development takes place, are peculiarly liable to become victims of nervous disease in the formative periods of their life, especially at the physiologic crises, such as puberty, pregnancy, lactation or menopause

This neuropathic diathesis may not only be *congenital*, but also *acquired*, and it can be produced in persons born of unhealthy parents by the excessive use and abuse of agents such as alcohol, opium, tobacco, tea, coffee, excessive study and physical strains of all kinds

Education —All education should be governed and based upon an intelligent recognition of physiologic laws of growth, and a proper adaptation to them There exists in every child certain laws of growth and corresponding capacities, the proper development of which depends, to a large extent, upon the general bodily constitution of the individual The natural law of progressive development is as gradual in its operation as the growth of trees and flowers, and if during its formative period, it unduly exercises or stimulates any organic function, the body will never be brought to the highest state of development of which it is capable

By thus interfering with the natural sequence of the evolution of the body, we disturb the normal equilibrium of its various parts, and thus seriously mar the harmonious relation which should exist between the mental and physical constitutions In a well developed organization the normal equilibrium of its every force perfectly balances, and to use the words of an eminent medical physiologist, "There should be no power in a higher center or ganglia to compel a lower one to do more than it is fitted or is capable of doing"

Clouston says "The fatigue following their normal use should be absolute, in themselves, to compel periods of *rest* and yet we all know that it is counted a great power and achievement for any man or woman to possess the power of being able to work, think, feel or wake, not according to their innate capacity, but according to his or her wish, or the imagined necessity of the occasion The exercise of such a power is really a want of nervous adjustment, and a physical imperfection not to be desired or encouraged, indeed, it is a very dangerous possession to those who inherit a neurotic diathesis" The functional activity of the brain and nervous system is established at different epochs, and perfected at different rates By cautious stimulation we bring it to its highest development, but by undue haste and excessive use we ruin its normal equilibrium

In the stimulating process of the educational period the cerebral cortex, which is the seat of all conscious mental action, undergoes a change of function corresponding to its excessive stimulation, and which, if long continued, culminates in a preponderance of nerve action, which is highly characteristic of the neurotic diathesis The nervous system, with the brain as its controlling center, rigidly obeys the natural law of evolutional precedence, and its functional energies are as gradual in attaining their full force and capacity as any other special apparatus of the body Anything, therefore, which has a tendency to force these powers and capacities, interferes with its normal equilibrium

It has become the custom of the present day for school and college professors to prescribe for their pupils the study of the more intricate problems relating to their special departments, believing this to be the one thing needful to accomplish any and every purpose in life Thus the ancient Roman law of physical excellence is completely reversed, and with us intellectual superiority and mental achievement take precedence of all aims and duties of life In the effort to excel, every other part of the organism becomes unduly subservient to the intellect, and the natural physiologic law of evolutional precedence is wholly ignored

To day the instruction of children is on purely business principles, without regard to their physiologic strength or capacity The largest amount of knowledge is to be acquired in the shortest time possible Rapid progress and intellectual supremacy is the highest test of a desirable school, and the teachers that are most in demand are those who are the most earnest and zealous in their work

A magnetic power of inspiration is the qualification *par excellence* in a teacher and that teacher is most in demand who can secure the greatest brain tension during the allotted hours of study

Intellectual achievement is the goal which all are seeking, irrespective of age, sex, mental or physical strength The home management of children also contributes its share to this brain tension Late entertainments, reading exciting works of fiction, social pleasures and strains of all kinds tend to bring about in them morbid growth

Nervous excitement is at a premium, and therefore prevails in the homes, school, church, and indeed every relation of life

A recent writer says it is a question whether the competitive examinations, as now carried on in schools and colleges, are not doing more to enervate the mind than to strengthen it Those who attain the highest honors are generally found to be diseased

Intellectually speaking, every mind has a track of its own To place all children on an equal mental footing, when they reach a certain age, is a violence to nature which brings its own equivalent in physical and mental deterioration

We recognize that certain causes produce certain effects, and we can see how the future generations are influenced by the good health and the proper mode of living of the present, and we must use every means at our disposal toward influencing those with whom we come in contact to study the laws of health, to reform their habits, and instruct in all matters that pertain to hygiene, and further in every way a more complete general knowledge of the human organism, and the laws and forces which govern it The short duration of life and the habits and modes of living of many persons can be attributed solely to their profound ignorance of themselves The consequence of their habitual neglect and ignorance entails upon their progeny untold misery, much of which might be prevented by a more intelligent understanding of themselves

The neurotic diathesis and its baleful influence upon the rising generation is not as well understood by the masses as it should be The reason for this may be explained to some extent by the prevailing false system of medical ethics which condemns any attempt on the part of the members of the profession to popularize purely medical topics The relation of the physician to society is not only that of a therapeutist, but also a conservator of the public health The full mission of a cultured physician is not complete if his educational attainments are solely bestowed upon the medical fraternity, and those coming within his range for treatment In addition to his strictly professional duties he owes a duty to the public In the past the attention and efforts of the profession have been too exclusively directed to the solution of problems connected with the cure of disease, and the great importance of its prevention has not been sufficiently recognized

The duty of every man who deals with his profession as a noble and humane science, is rather to point out the methods of preventing occurrence and eradicating, if possible, latent constitutional defects, than to confine his attention to the treatment of its active manifestations The vast amount of preventable disease which is filling thousands of premature graves and destroying the hopes and happiness of both the young and the old in every community of our land, certainly demands the earnest attention of the medical profession

So long as we remain indifferent to this great and growing evil, just so long will nervous disease continue to increase and swell the rate of premature mortality Several of the more progressive members of our profession both in Europe and America, now recognize the great need of a more general dissemination of medical knowledge among the masses, and are advocating its adoption as one of the most powerful agents in the prevention of the spread of nervous diseases

"Any work," says Dr Mann, in his recent work on physiologic medicine, ' that we, as physicians, do toward influencing the public to study the laws of health, to reform their habits of living, to promote the use of baths, to encourage temperance, ventilation and due exercise, and to further a more complete knowledge of the human organism and the laws and forces which govern and regulate it, and in diffusing a knowledge of all the means necessary for the preservation of good health, will produce its exact equivalent of results in the prevention of disease We shall thus develop in the masses an intelligent, self-helping character, tending to robustness of body and robustness of mind "

Another favorable field for a more thorough practical drill in matters pertaining to mental hygiene and the study of physiology is the public school I am not unmindful that some attempt has been made in this direction, but it is merely an attempt

Very few pupils (and shall I say principals of schools) realize the full force of one of the first principles of physiology, viz, that within certain limits the growth of an organ is in proportion to its exercise, and that all excessive exercise is followed by a corresponding depression If this law were thoroughly understood and obeyed there would be less headache and disc nted to the public school In cases where th stitution is inherited the morbid inherit terious and necessarily fatal doom, c to overwhelm its victim It is p which can be nd even e able to explain fully its intricate pathology, but we know it manifests itself in a great many distressing forms of nervous diseases, and the wise physician, after recognizing the morbid taint, anticipates the pathologic conditions likely to arise, and therefore does not neglect to advise means necessary for its complete removal

The nervous temperament predominates in American women, which is now recognized to be due to some trophic lesion This being readily transmissible from parent to child, if we are to avoid its continuance in the young we must resort to such methods as will produce a better type of physical constitution and mental stamina Hence the great indication in the prevention of nervous diseases, is to harmonize the physical and mental organizations in such a manner that their correlative forces equally balance

Marriage —In every individual two streams of ancestry mingle, each furnishing its own specific mental, moral and physical characteristics As a general law, the stronger character predominates, but never so strongly as to completely overcome the weaker Pure blood should certainly be the desire and lofty ambition of every individual The promulgation that "the iniquities of the fathers shall visit the children, unto the third and fourth generation," can not be gainsaid Our country to-day stands in need of more healthy men and women, and one way to secure these is by wisely regulating matrimony

Every marriage acts upon society in a fourfold relation, by first affecting the conjugal pair, second their progeny, third their relatives, and fourth the community in which they live

I believe in certain cases, *marriage should be governed by law*, for in the light of facts, who can truthfully argue that it is nobody's business whom we marry? Habitual governmental regulation of marriage comes with higher grades of civilization

The Spartans regulated marriage with sole reference to the good of their republic, men were subjected to severe penalties if they married too early or deferred it too late Unhealthy children were destroyed as unfit to live (And here allow me to say that such a movement is already projected in this country) Every care was used by the Spartans to insure the health of infants and children But instead of studying the interests altogether of the state and nation, we, as a Christian people, should view it from a more humane and philosophic standpoint

Generally speaking, no special effort is now being made on the part of parents and guardians to choose proper society for their wards Those easy American habits which permit, unchecked, the free social mingling of the young without regard to the laws of heredity, often result in marriage and intermarriage of consumptives, epileptics and other diseased and defective individuals, while the less demonstrative insane and more demented specimens of humanity have also free access to all classes of society Even the known vicious and morally perverse often form unions in the more devout families We know too well the sad import of such thoughtless and ill-assorted marriages, especially, therefore, is it our duty to impress upon the minds of parents the necessity of wisely informing their children on these matters, lest ignorance prove a future source of evil The responsibility of the medical profession in relation to the coming manhood and womanhood of our race can not be overestimated

The American, however, is accustomed to regard his individual rights to the exclusion of all others, and the conviction that a man can be what he wills to be, is lodged in the most intimate fiber of his being Such an idea, however, is erroneous, especially when subject to the laws of heredity, and the results of its misapplication are self-evident

Physicians who have children growing up under their professional care should endeavor to have them well developed physically, even if it be at the expense of their education We too often sacrifice the constitution for what is deemed educational necessities

The prime necessity in our children is to have plenty of bone, blood and muscle, with an accurate balance between the physical and the nervous system, and if something has to be sacrificed let it be their education, and not their physical health

The children of neurotic constitutions should be kept fat from birth, and when they arrive at the school age their brains should not be forced

As a general rule, these children are precocious, hypersensitive and possessed of a vivid imagination Their parents and friends admire their quickness to learn, and urge the teacher to push them forward to the fullest extent, that they may out-distance all competitors All such precocity should be discouraged and condemned, as it is said by the best authorities to be a sure sign of biologic inferiority

Dr Porter of St Louis, in his studies of school children states "that mental ability is on the average greater in large children than in small children of the same age"

In some recent research in the schools of Kansas City I found, however, that the precocious children were invariably below body weight and poorly nourished

Our local city authorities are too prone to ignore medical aid in their sanitary and educational legislation No class of persons are better prepared to give useful advice in such matters than the scientific physician More especially is this true of education, and a wisely selected medical board should be appointed in every city to inspect the public schools at regular intervals and determine which children should and which should not be allowed to study the more difficult branches

It is nonsense to regard the child's age as the criterion of its mental strength and capacity It seems far more logical and scientific to allow the child's *height* and *body* weight to govern this Definite standards of weight should be fixed for every age and height, and every school boy and girl having a nervous diathesis, whether it be congenital or acquired, should be weighed at regular stated intervals, and if found to be below the fixed standard they should be compelled to forego some or all of their studies and be placed under proper treatment until the loss in body weight, at least is recovered

The first evidence of mental deterioration is manifest in a loss of body weight Children of nervous constitutions should be taught to lead regular and systematic lives, and the necessity of developing fat and muscle, as well as the dangers attending such neglect

It is outside the province of the responsible duties of a principal of a school to determine which child shall, and which shall not study hard It needs a skilled physician or neurologist

Such a plan would also prevent much undeserved censure of the principals and teachers by the parents complaining that their children had been unnecessarily retarded in their grades

We must be more active and alert in this direction, and not until we, as a body take a more decided stand, can we hope to successfully stem the rapidly advancing tide of both organic and functional nervous diseases

If it be true that the physiologic nerve cell is limited in its capacity, and that its normal activity results in the expenditure of a certain amount of force which, when discharged, presents changes corresponding to fatigue, and that a certain amount of rest is not only capable but necessary to restore or regenerate its normal function, in the absence of which, changes corresponding to its inanition occur, then, clearly, the duty of the physician is to use all possible means to secure the needed *rest* for all morbid conditions of the nervous system in which nervous irritability and instability are the chief clinical criteria, and those which form so great a part or the subjective phenomena of the purely functional neuroses and psychoses

---

DEGENERACY, ITS CAUSES AND PREVENTION

BY ARTHUR ROWLEY REYNOLDS, M D

PRESIDENT OF THE BOARD OF STATE COMMISSIONERS OF PUBLIC CHARITIES OF ILLINOIS AND LATE COMMISSIONER OF HEALTH OF CHICAGO

Practically all recent books and essays upon the subjects quote statistics to prove a startling increase of insanity, of criminals and of pauperism They either state or intimate that the race will soon be overwhelmed by the number of persons of this character, unless something is done to prevent them from procreating their miserable kind

Before we accept this gloomy conclusion, we should study the matter and see if the statistics may not be faulty We may also, with profit, study the conditions that are in the way to prevent those who are normal in their development from continuing so indefinitely through succeeding generations, as well as to recognize and study what influences are at work to counteract degenerating tendencies

There is ground for hope that some of the apparent increase shown by statistics is not real, but due to the greater care in the census enumeration of later years Moreover, insanity and other mental defects are now treated as a disease and misfortune, and more frequently come to light while formerly they were too often considered a blemish and disgrace and hidden from view We may draw some consolation, too, from the fact that latter day segregation of many of this class will prevent their reproduction and favorably impress the figures of the future Nevertheless, we recognize that whatever arguments there may be against the correctness of the statistics of the question, we yet know that the dependent individual is most numerous and a great and ever increasing burden to the state

Economic conditions, new to our generation, have arisen with the vast application of steam and electricity and have played a part in the enormous growth of cities The furious passion for money pervading all classes, and the sway its possession gives in business, in politics, in society, in religion, in courts of law, in legislative bodies, is lea[illegible] Great wealth has led to a des[illegible] enhance its power, and giant co[illegible] formed, enormous enterprises undertaken, all of which gives a demand for men at wages and destroys the individuality of small concerns, while the fall in the price of produce has made farming unprofitable These conditions make rural people turn a more willing ear to the promise of shorter hours and regular stipend, and they swell the stream setting toward the cities The farmer forgets his freedom and his independence and recalls it too late, when he finds himself a mere cog in a great machine in the city, and no hope of relief when his employment is gone He is then in poverty and hope dies within him He is tempted or driven to do evil and may never be able to reform He has not his native trees for company and inspiration There are no flowers to cheer, no calm for reflection, no quiet for study Children born and reared under such circumstances start the race of life with a serious handicap

No argument is needed to prove the power of heredity It is seen every day in the development of the trotting horse, whose breeding is regulated with such nicety that the height, weight, color, speed and even the cash value of a colt can be told, almost to a certainty, before it is born The state undoubtedly should make use of this knowledge to perpetuate and upbuild the race, as an offset to the increasing tendency that density of population, through vice and disease, makes toward degeneracy

In our own country we suffer from the additional burden of imported dependents Indeed it has been said that foreigners furnish one eighth of our population one-third of our paupers, one-third of our criminals and one-third of our insane It is true, I believe, that we have a law of Congress to prevent the importation of dependent persons So long, however, as the conditions of life are easier in our own country, the degenerates of Europe and Asia will find their way to our shores

A strict medical supervision of all marriages is strongly advocated by some writers, as a safeguard against the increase of this class of persons It is unquestionably wrong for degenerates of a pronounced type, and those who are dependent, to propagate their kind, and there can be little doubt that the state has a right to step in and restrain the weak or the willful of these classes, through the application of medical knowledge, to the case of every applicant for a marriage license, but whether or not this will cure the evil is a question that should be carefully studied It is not the purpose of the writer to dampen the ardor of those who would regulate the evil by law, on the contrary to urge it and freely avow belief that steps should at once be taken, beginning at the marriage license windows of our country, to prevent the union of those who, by the almost unerring law of heredity, will reproduce a brood which will be a charge upon the state or a burden to society Proper laws, intelligently enforced, will directly restrain a great many It is our belief, however, that their chief use will be to form a focusing point, from which knowledge shall radiate We believe further that it is only through the proper education of the masses that those unfit to reproduce their kind will be restrained And we believe [illegible] er even though [illegible] that the race is [illegible] one [illegible] her, where the [illegible] e unf [illegible] equally true t[illegible] t [illegible] ng on [illegible] ere t [illegible] laws an [illegible] nd statutory enactments are of but little value, unless backed by a healthy public opinion But there are agencies constantly at work to counterect the degenerate tendencies that should be considered before we despair of the race

While it is necessary to look evils squarely in the face, it seems wrong to enumerate them too often, to discant too loudly upon the ills that beset us, or to see only the dark side of the picture Human nature is prone to brood over the sorrows and trials of life The uncanny things are too apt to be kept prominent and we are too likely to forget the cheery, bright and sunny side of affairs The world contains more sunshine than shadow, more joy than sorrow, more smiles than tears, more righteousness than sin, more good than evil, more charity than theft Adam's sin is repeated still, but there is an ever-progressive spirit of the Nazarene pervading every day life

It is well to prevent the degenerates and dependents from procreating, but it is infinitely more important to correct whatever there be in our civilization that drifts toward degeneracy Human beings crowded together so close that the home loses its individuality, its sanctity and its seclusion, or that vitiates the air that is breathed, that makes artificial feeding of old or young necessary, that pollutes the drinking water or in any way hampers physical growth Whatever there is that blunts the moral sense, that whets the appetite for alcohol, that excites the passions or gives opportunity for licentiousness must be wrong All these evils are fostered by too close living in tenements, whether located on the boulevard or in the slums, and just as sure as a cloudy sky portends the coming of the storm, such conditions lead on directly to drunkenness, crime, idiocy and insanity Whatever is being done, or whatever may be done to make country life profitable and possible is an aid to segregation and must therefore be a step in the right direction The trend of population toward large cities is not a good omen for the race d calls loudly for legislation that will turn the cur- nt back again The great and rapid growth of our ties, that receives so much admiration and is quoted such signs of prosperity and greatness, will ultimately result in a plague upon humanity if some wisdom does not appear and set the tide the other way Can it be that the crowding will go on till the curfew will be necessary to segregate the young in their homes, that the evil of street association, as a school of vice and crime, will be lessened? It is well to pause and inquire where is the profit, in the end, of clustering of industries in large cities, if sweater's dens must be the accompaniment It may be well to consider whether or not those having knowledge of medical sanitation and sociolgy should not have a larger place in our legislative assemblies It seems that their valuable knowledge should be used in deciding our laws of immigration and other legislation relating to the welfare of the race, while it would lessen the too common tendency to decide such grave questions upon the sordid demands of barter and exchange

We have with us now and always have had splendid and powerful agencies, operating with vigor, as a stay to crime and a help to humanity Chief among these is the church through all her divisions and denominations, for whatever the differences as to church government may be, their teachings are as one on the question of morality and right living

I wish, however, to speak more particularly of an agency that is paramount to all others in its influence toward the regeneration of the race, an agency that has already done a vast amount of good and that promises, if properly backed and intelligently followed, to solve the problem, an agency that strikes almost at the root of the evil, an agency almost divine indeed—for it is none other than the new woman I do not refer to the new woman of newspaper creation —not the woman who hopes by copying the follies of man or his wearing apparel, to emancipate herself Not the woman who would wage a war of strife and contention with men She is not new—she is as old as civilization itself

The real new woman understands that there is within her an inherent and natural power to command the actions of man and sway him for good or for evil She realizes her power, and that hers is the enormous responsibility to shape and control the destiny and perpetuity of the race She realizes that it is her high and divine privilege to be the mother of mankind She realizes that it is among her first duties to equip herself, mentally and physically, to graciously bear the joys and responsibilities of maternity. She realizes that there is no loftier mission on earth than to fashion the character and train aright the intellect of the growing child She realizes that the budding boy is the coming man She realizes that it is a crime for man to grow so grasping as to enslave his fellow creatures of either sex She realizes that the good things of this earth are God's bounty and intended for all his children alike She realizes that the mad race for wealth, with its rapid concentration "makes countless thousands mourn ' She realizes that the frenzy for gold is every day enhanced by the demands of some of those of her own sex, as they struggle to reach the summit of fashion and social power She realizes that the mother is largely responsible for the traits of the child, other than those of heredity, and that it requires no more time to learn and love the ways of purity, than to learn the ways of vice and iniquity She realizes too that proper training is the best preventive of perversions of every kind She has established and is all over the country conducting branches of the greatest institution in American history—I refer to the kindergarten

The kindergarten has reversed the old order of things, when the daughters of the poor and uneducated, and perhaps the vicious, were made the companions, the guardians and instructors of children in the homes of the rich Now young ladies of good position in the world graduate from universities to take positions in the kindergarten, qualified to mold, fashion and discipline the minds of children of the humblest, beginning with the child at the very dawn of its intellectual development Devotees of this new cause deem it a privilege to work all day in the creche, caring for children of mothers who must toil for daily bread

The new woman believes it is a perfectly normal desire to want to wash and dress, to entertain and caress a helpless babe, even though it be of lowly birth, and if the babe should be her own, she counts the moments she is forced to be separated from it She feels pity toward her married sister who dwarfs her maternal instincts, or denies herself the boon of motherhood, or who shuns the society of the children she has unwillingly borne The new woman sees in life upon a farm better discipline for the mind than can be found in the greatest counting room She sees that the same farm can do more for the physical development of men and women than any manual training school in the land She sees that the music of the birds inspires deeper thoughts of God and Nature than all the grand organs in the universe, that the sighing of the wind through the trees and the patter of the rain on the roof inspire the loftiest emotions

The new woman is she who founds homes and settlements among the poor, and successfully conducts them She consoles the needy in their trouble and feeds them when they are hungry She encourages the idle to work and helps them to secure it and if necessary she instructs them how to perform it She founds and conducts useful societies, classes, schools and clubs of every sort among the poor Her spirit and her genius build fresh-air sanitariums, floating hospitals; and in the summer time sends from the alleys and slums the debilitated weaklings to the green fields, the sylvan groves and the babbling brooks, to drink in the inspiring delights and breathe the pure air of the countryside I will not attempt to enumerate all the institutions she is working through, for they are well nigh countless and daily multiplying

When the new woman's hand is sought in marriage, she is likely to have inquiry made as to the young man s health and his morals, rather than inquiry as to his bank account What his wealth in the great distinguishing characteristic that elevates him above the animal world—his manhood, his judgment, his intelligence? It is through the new woman that society will eventually come to apply the same rule and exact the same standard of morality for men that it does for women and eventually elevate him to her plane

The new woman has learned the terrible cost in pain and suffering to her sex and her offspring that so frequently comes from a union with dissolute men She has learned through the advance of medical science, that the harvest reaped from a sowing of "wild oats" in her husband's youth is too often one of disease and death to herself and a pitiful inheritance to her child

Higher education through schools, great universities and libraries is not enough Kindergartens should be founded in sufficient numbers to reach all the young The new woman will multiply the kindergartens and reach the degenerate or wayward before habits of thought or action are formed and do for the infant mind all that training and example can do

Through the present work of the new woman and its future development must come the public knowledge and the public sentiment that will lead to the necessary reform to let daylight through the slums, to raze the unsanitary tenement to the ground, to pull down the towering buildings that harbor miasm in their shadow, that will make it possible for human beings even in cities to live on the surface and not be forced either into the air or under the ground

Through this direction of forces, cottages will be built for all so that man can return to his primal condition Even the very poor will not be denied free access to God's sunshine, pure air, green grass, the shade of trees or the beauty and fragrance of the flowers

A vast number of holy influences are constantly at work that realize the necessity of proper care and training of children while they are young Let us hope it will go on till our philanthropists and our State legislatures will see the economy of laboring more for institutions for the young, for if they be trained aright, it surely means economy in hospitals, asylums and prisons

THE PSYCHO-NEURAL FACTOR IN SURGERY

Read at the Meeting of the Mississippi Valley Medical Association at St Paul Minn 1896

BY C H HUGHES, M D

PRESIDENT OF THE FACULTY AND PROFESSOR OF PSYCHIATRY AND NEUROLOGY BARNES MEDICAL COLLEGE ST LOUIS HONORARY FELLOW BRITISH MEDICO PSYCHOLOGICAL ASSOCIATION AND OF THE CHICAGO ACADEMY OF MEDICINE

ST LOUIS MO

As a thorough knowledge of general and special pathology is essential to the soundest surgical judgment as to the propriety and necessity of an operative procedure, so is a knowledge of the nervous system of the patient and the relation of his nervous system to the local disease found essential to proper diagnosis and prognosis The time is coming and now is when the surgeon should have wide neurologic and psychiatric knowledge in order to avoid fatal mistakes and to most successfully practice his art The manner in which the necessity of a grave operation is announced may to certain psychologically unstable constitutions pre-determine a fatal issue, or it may give to a doubtful issue a possibly favorable result There are some constitutions so neuropathic and psychopathically predisposed that the shock of such an announcement would precipitate a crisis of mental alienation, and it were better that the proposed operation should be abandoned than insisted upon under such circumstances, or that the patient should be gradually approached and prepared by cautious speech and suitable precursory, reconstructive and tranquilizing neurologic treatment Some patients before being operated on should be made almost entirely over in the tone of their nervous systems and some should be let alone, tranquilized and made comfortable and allowed to die in happy euthanasia What, for instance, is the use of exsecting a far-advanced cancerous uterus after the cachexia has long persisted and the nerve centers have become irreparably neuropathic and the neurasthenia has become profoundly irreparable from the prolonged pain and insomnia The rational process would be to stop the pain and insomnia, correct as much as possible the neuratrophia that exhausts and makes the patient's last days comfortable by neurologic and antiseptic treatment and the best surgical suggestion without the knife In fatal surgical results the reputation of operative surgery suffers often because overlooked neuropathic conditions were at fault

In my judgment the previously applied skill of a neurologic clinician would postpone many operations indefinitely which are now fatally performed and properly prepare other cases for the surgeon s knife and a successful surgical issue, which are now doomed when the operation is decided upon, because conditions of endurance of the operation are not in the nerve centers of the patient

The cause and effect of psychic shock in different patients are not always considered as they should be by either physician or surgeon The possible evil effects of words and acts at the bedside or before an operation that tend to paralyze or even produce a paresis of hope [illegible] not always duly considered The surgeon who bluntly announces to his patient, after revealing the necessity for the knife and having all things ready, "now I am going to operate, the proceeding may kill you, but you would be better off dead than alive as you are, let us hope for the best," must have a strong-nerved, brave subject to not be somewhat depressed by such an announcement, and such a depression before a further depression of vital centers by chloroform or ether, even in the strongest nerved is not good clinical practice It doeth not 'good like a medicine " Such a procedure may have the virtue of candor to commend it, like the candid announcement by the physician that his patient is likely to die If he is saved it will be 'by the skin of his teeth " Recovery is not the rule when such premature prognoses are announced, sometimes because the patient could not have recovered by reason of an incurable malady and sometimes of the vitally depressing effect of the speech that destroys hope and removes its buoyant influence from those vital nerve centers that influence the metabolisms of the organism and the assimilative processes of organic life and reformations of tissues

In our intercourse with patients, medical or surgical, the untoward and often fatal influence of depressing mental suggestion on the patient should always be avoided Hope, that springs eternal in the human breast if we do not interfere with it, is itself a buoyant medicine, and faith in the physician or surgeon is therapeutic power that should never be rudely shattered by us Candor is to be commended, but it can be too bluntly displayed and often is, for the welfare of our patients Besides, the physician's or surgeon's judgment may be at fault It often is There is more vital resistance and power of repair in the patient than the medical or surgical attendant thinks or knows Vital power is not always a definitely measurable quality, depending as it does, upon ancestral factors in the upbuilding of the constitution—the cerebro-spinal axis and the sympathetic system of the patient—of which we are never fully cognizant The patient should always have the benefit of this doubt in our prognostications before him or to him

The little surgeon who pompously displays his tray of instruments before his trembling patient, and to his woful, wondering mind descants upon the operation he is about to perform and the chances of recovery or displays a nonchalant, unfeeling mien, acts in an unprofessional manner and does not increase his patient's chance of getting well quickly And the great surgeon who takes his patient into the operating room and places him while conscious on the table, himself with instrument in hand, while white-aproned attendants gather around the victim, approaching with sponge and bottle and instruments and appliances of the impending operative procedure, is not so wise a surgeon and does not so fully consider the effect of depressing psychic influences as he who chloroforms the intended subject of an operation in another room or in the same room without these depressingly suggestive influences

Had I continued the active practice of surgery (of which I once had, as you know, ample clinic experience) I should never vaunt the implements of my art before my patient, at least before he should recover from the operation, nor anesthetize him in the presence of any depressing influences Where practicable, I would for purely elevating psychic effect, begin the administering of the anesthetic in the most cheerful room I could prepare I would drape its walls with suggestions of hope and inspirations of courage I would have nothing about me at that time suggestive of blood I would cheer him so far as I might without falsity, mention similar cases, if I could, that had undergone his approaching ordeal successfully and let him take his operating couch and anesthetic as "one who lies down to pleasant dreams " I would proceed thus because I am a psychologist and have added something more than operative skill to previously acquired medical knowledge I would be as tender with him about inflicting the mental pain of dreaded apprehension as "one who would not needlessly set foot upon a worm " I would do thus, not only because it would be the dictate of tender feeling, but because a sound psychology and psychiatry enjoin it

THE STATISTIC EVIDENCES OF THE VALUE OF VACCINATION TO THE HUMAN RACE, PAST, PRESENT AND FUTURE

Read before the American Medical Association at the Jenner Centennial Celebration held at Atlanta, Ga , May, 1896

BY EUGENE FOSTER, M D

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE AND STATE MEDICINE AND DEAN OF THE FACULTY OF THE MEDICAL DEPARTMENT UNIVERSITY OF GEORGIA AUGUSTA GA

(*Continued from page 911*)

Now to a circumstantial examination of the charge of transmission of syphilis by vaccination

The medical literature of every civilized nation has been ransacked for the purpose of substantiating this charge "The London Society for the Abolition of Compulsory Vaccination," ever active in seeking and disseminating all information detrimental to the cause of vaccination, has put together all cases of alleged vaccinal syphilis which its active investigators could hear of Here is a copy of the original paper from that society, received by me in 1884 ‖

VACCINO SYPHILIS

The following is list of authenticated and published cases¶ of transmission of this one disease alone

Lancereaux has published the following cases of vaccino syphilis

By Cerioli	40	By Lecoq	2	By Chassaignac	1
By Tassani	46	By Galligo	14	By Hérard	1
By Surgeon B	19	At Rivalta	46	By Adelasio	2
By Hübner	8	By Trousseau	1	By Monell	1
By Marcolini	40	By Maronni	34		
By Viani	2	By Devergie	1	Total	258

To these I have added the following

By Hutchinson	24	At Lebus	18	By Fuqua	52
By F Smith	1	By Depaul	59	By Cullimore	1
By Hulke	1	By Sebastian	1	In Algiers	58
By Oldham	3	By Collins	2		
				Total	478

M Briquet appropriately says "A competent observer and a complete observation, reported with such details as render the statements capable of being checked by the reader, are indispensable requisites for establishing the reality of an ordinary fact in medicine, and if for establishing an ordinary fact, how much more when the facts alleged are confessedly so rare, and so contrary to all previous experience, as these must be admitted to be " To correctly investigate the question of vaccinal syphilis we must first determine the question of inoculation of the lesions of secondary syphilis Experiments by competent observers have demonstrated that condylomata, ulcerated tubercles, psydracious pustules of ecthyma, pustules of acne, mucous patches and the blood of syphilitic subjects, may be inoculated into the constitution of the person not already infected with syphilis Now, it is an admitted principle in the teachings of syphilography that the secretions from pathologic lesions, not themselves syphilitic, although occurring upon the bodies of syphilitic persons, do not contain the virus of syphilis, unless admixed with blood Gonorrhea upon a syphilitic patient reproduces gonorrhea by inoculation, and not syphilis, and the same is true of chancroid All of these lesions of secondary syphilis, except the blood, may be eliminated from this discussion, for we can not imagine how any other of them could contaminate vaccin matter in its rational propagation

---

‖ From my paper before American Pub Health Assn

¶ These cases have been fully examined and a brief analysis of some of them will be presented later on

Is the effort to inoculate a healthy person with syphilitic blood invariably successful, and, if not, what proportion of success will attend these efforts? The following presents the results of all such efforts to be found detailed in the most authoritative works upon syphilis

Name of experimenter	Number of inoculations	With success	Without success
Anonymous surgeon of the Palatine	9	3	6
Waller	1	1	
Gilbert	1	1	
Pellizzari	5	1	4
Lindwurm	1	1	
Thiry	4		4
Lalagrade	3		3
Diday	20		20
Total	44	7	37

Thus, gentlemen, we see that where intelligent physicians, bold enough to test the matter, after deliberately and carefully endeavoring to produce syphilitic infection by inoculating healthy subjects with syphilitic blood, failed in 84 per cent of all such efforts, only those efforts were successful where as by Pellizzari, the anonymous surgeon of the Palatine, Waller and others, large surfaces were denuded and syphilitic blood in large quantities kept for many hours to the denuded spots

It is, of course, impossible in this discussion to enter into an extended or minute examination of the cases of alleged transmission of syphilis by vaccination The following embraces nearly if not the entire list of reporters of vaccinal syphilis, as given in the best works upon syphilis

Name of Reporter	Number Vaccinated	Number Infected	Number not Infected
Cerioli	46	40	6
Tassini	64	46	18
Surgeon B	24	19	5
Hübner	13	8	5
Monell	1	1	
Marcolini	40	40	
Viani	2	2	
Lecoq	2	2	
Galligo	14	14	
At Rivalta	63	46	17
Trousseau	5	4	1
Marone	34	34	
Devergie	1	1	
Chassaignac	1	1	
Hérard	1	1	
Adelasio	2	2	
Totals	313	261	52

HUTCHINSON S CASES

Series of Cases	Number Vaccinated	Number Infected with Syphilis	Number not Infected with Syphilis
First	12	10	1
Second	26	9	17
Third	13	1	12
Fourth	Unknown	1	Unknown
Fifth	Unknown	2	Unknown
Sixth	Unknown	1	Unknown

It is absolutely necessary, in an "investigation of alleged cases of vaccinnal syphilis, to ascertain, 1, whether we are really dealing with syphilis 2, whether, if this be so, the syphilis is not hereditary and a mere coincidence or evolution of vaccination, 3, whether, if it be acquired syphilis, this has not some other origin unconnected with vaccination, or attempt to vaccinate, 4, whether, if the acquisition of syphilis be reasonably traceable to vaccination, or attempted vaccination, there is evidence, direct or presumable, that the so called vaccination had been done from a genuine vaccin vesicle, and that the products of that vesicle had not been mixed with some of the inoculable products of syphilis Not till this was settled would any question arise about admixture of blood The interest and importance, after all, of the cases in which vaccination is alleged to have communicated something beside its own infection, turn entirely upon whether the vaccination had been performed with unmixed lymph of genuine vesicles—vesicles about which no competent person would make a mistake '

Seaton (Handbook of Vaccination) appropriately says 'It must obviously be impossible to discuss at length, within such limits as in a general treatise of this kind could be allowed, all the cases that have been cited as evidences of the communicability of syphilis by vaccination The most satisfactory course will be to examine carefully three or four cases typical of the kinds of proof which have been advanced of this occurrence "

The following is an extract from his review of alleged cases of vaccinal syphilis "1 An epidemic of syphilis reported by Cerioli as having occurred in 1821 (inquiry made eight months after its orgin The account given of this epidemic is of the loosest kind it was not proved, or even alleged, that the child, from whom the lymph supposed to have been the origin of the outbreak was taken, had ever had syphilis), 2, another epidemic in 1841, seen also by Cerioli (investigated likewise after a very long lapse of time), the child from whom the lymph was taken never had syphilis but it was said that the year before his father had had syphilis "

Surgeon B "It appears that in a town in Germany twenty four people belonging to different families, were in February, 1849 (some on the 13th, some on the 14th, and some on the 15th), revaccinated, as they supposed, by him There is no statement of vaccin vesicles having been produced in one of the cases, but at the end of three or four weeks (*i e*, the ordinary period of incubation of syphilis), ulcerations of a syphilitic character began at the points of inoculation in nineteen out of twenty four persons operated on, and these were followed in due course by constitutional syphilis Here was syphilis, but no vaccination What could have been the cause of it? The vaccinator who was inculpated asserted that the operations were all done with lymph from a child who was *fort et sain* and who, having been vaccinated on the 4th of the month, had regular vaccinia We shall see immediately how far this statement was borne out, but it must first be noted—and is an illustration of the want of precision generally attending these accounts—that we are nowhere distinctly told whether the so called vaccinations, or any, or which of them, were done direct from the child, or whether the stuff taken from it might not have been collected on glasses, points, or tubes For all that appears to the contrary, there was at least the possibility of a mistake (such as has happened many times with regard to the matter of inoculable diseases) of taking lancets or glasses or tubes charged with one kind of inoculable matter instead of another But, assuming that the matter used came from the source indicated, what was the state of this source? Though it was said to be from an infant *fort et sain*, and that this was *surabondamment démontré par plusieurs témoins*, a different account was given by other witnesses, and a doctor, who saw the child on the 21st of February, a week after the lymph was taken off, when of course no suspicion of anything wrong had yet arisen, testified to the existence of some erythematous eruption, which was said to be like syphilitic roseola, and it died on the 24th, three days after his visit, of hydrocephalus But, more importantly, what was the state of its arm? It turned out that, according to an eye witness, there was on the eighth day of the child's vaccination not a vestige of vesicles, *aucune trace de boutons*, and yet two days later, the account tells us, several vaccinations were performed from it and lymph continued to be extracted from it for two days "

"In Hubner's case—a case of malpractice—there could be no doubt of some children having been syphilized, but no investigation of the circumstances was made till eight months afterward, and the account of the so called vaccinations (in most of which it is quite certain, and admitted, there had been no proper vaccine effect), was only what could be got from the statements and recollections at that interval of time, of the mothers "

Trousseau's case "A young woman was under treatment in the wards of the *hôtel dieu* for a uterine affection apparently of a non specific character, at a time when there were some small pox cases in the hospital, and wished to be revaccinated This was done by three punctures on each arm, from a healthy child at the time, and which, for anything that was ever known, never exhibited any taint Four children who were vaccinated with its lymph at the same time with this young woman went through vaccinia in its regular way and never had any subsequent syphilitic affection On the young woman s arm slight papules only arose, and the revaccination was looked upon as having failed She remained in the hospital a month after vaccination, fully the time necessary for the syphilis if there had been any imparted by the vaccination to have incubated, and she went out without anything the matter with her arms At the end of another month she attended at the hospital for treatment of her uterine complaint, and showed them two sores on one of her arms the character of which was not at first recognized but which turned out to be undoubtedly syphilitic It was not known at the time but was afterward ascertained, that she was a young woman of very loose character Now, assured by no one who knows in what extraordinary situations chancres have been met with such as the cheek the corner of the eye, in every sort of situation in which there could not be any, and never was any, suspicion of vaccination can say this was a case entirely free from fallacy as to the source of the syphilis '

"The occurrences at Rivalta, to which so much interest has attached, were of a different kind In 1861 there occurred in this village a very remarkable syphilitic epidemic Three similar epidemics are said to have been noticed in different places before—in 1814, 1821, and 1841—and if we include an account given (though not till some years after the occurrence took place) by a Dr Marone, a fourth in 1856 It is certainly very singular that all these epidemics should have occurred in Italy, and none resembling them met with elsewhere Whatever their origin, the facts are of the deepest interest, a number of children affected at one time with syphilis, these infecting their nurses and mothers, the mothers infecting their husbands, the children infecting one another by the act of kissing, or by the spoons used in feeding and whole families infecting one another by merely being huddled together in confined and crowded dwellings For it must not be supposed that only persons who were at the time the subjects of vaccination were the sufferers Various epidemics of this kind, quite as singular and quite as inexplicable, have occurred under circumstances entirely unconnected with vaccination, and indeed before vaccination was heard of * * * In the five epidemics specified in the beginning of this paragraph, a vaccinal origin was alleged, and this was made in the Rivalta case the subject of careful inquiry by a scientific commission Unfortunately, however, the inquiry did not take place till four months after the outbreak, and as in no single case of the children said to have been syphilized by vaccination had any application been made to a medical man on account of the condition of the arm, facts and dates on the exactitude of which everything depends had to be got as they could at such distance of time from the testimony of the villagers, for the most part ignorant and prejudiced Under these circumstances, it is not surprising that different conclusions were arrived at, and though Dr Pacchiotti and the other commissioners, after a most careful and painstaking inquiry, reported themselves satisfied of the vaccinal origin of the disease, Sperino, who also went to Rivalta and there investigated the circumstances, and treated some of the cases afterward at Turin, was equally satisfied that their origin was independent of the vaccination The story, as regards the vaccinal origin, is this A child (Chiabrera) apparently in good health, but really incubating syphilis, was vaccinated with some lymph obtained in a tube, this child's arm was used on the tenth day for the vaccination of forty six children, and one of these forty six children, named Manzone, again on the tenth day furnished lymph for vaccinating seventeen children Of these sixty three children, forty six had within two months a disease considered by the commission to have been syphilis—the syphilitic symptoms having manifested themselves in some cases within ten days, and as a mean at twenty days from the vaccination Now, in explanation of these events, can we admit that the matter taken from Chiabrera's arm contained the contagion of the constitutional syphilis, which at these intervals of time the children manifested? Not, assuredly, unless we are prepared to give up all we have been taught as to the incubative period of constitutional syphilis For it would have required from three to five weeks for that disease to manifest its primary symptoms [Lee gives the period of incubation at from three to seven weeks Rollett gives a mean of twenty six days, and out of a large number of cases there was only one case in which it was under fifteen days In four cases, in which the inoculation was by blood, the minimum was twenty five days and the maximum thirty five As recent testimony on this point, it is proper to state that Hutchinson says, "The period of incubation, prior to the first specific induration, will usually be five weeks"[43]] But if this teaching has been erroneous and true constitutional syphilis can produce its primary symptoms within ten days, then indeed, we can understand how, if syphilitic matter was mixed with the lymph, either in the original tube or through the lancet employed in Chiabrera's vaccination, an irregular vesicle might result, such as that stated in Sperino's experiment with soft chancre, which Baumés and Viennois held to contain the two viruses mixed It must be remembered that we have no reliable account whatever of what was the sort of vesicle or result on Chiabrera's arm, from which the so called vaccinations were done From such a result as Sperino's experiment affords, a careless man might, a careful man would not, take what he called lymph, and I have very little faith in the proceedings of any one who evidently habitually used tenth day cases We might not really, then (that is, supposing the incubation difficulty got over, which it must be, or else the Rivalta cases as connected with vaccination fall of themselves) have any difficulty in accounting for the propagation of syphilis, for hard and soft chancres would fall in the same category But we should have more hesitation as to whether vaccinia also might be communicated at the same time, and, in fact, in what degree the Rivalta children who were syphilized were also vaccinated, it is impossible to say I can quite conceive that if the vesicle on Chiabrera's or Manzone's arm was all like that produced in Sperino's experiment, some spurious vaccin result might follow in some of those vaccinated from them There is certainly no satisfactory evidence of any of the children ever having had regular vaccinia"

(To be continued)

SOCIETY PROCEEDINGS

Chicago Academy of Medicine

The regular meeting of the Academy was held Oct 15, 1896

Dr W XAVIER SUDDUTH acted as Chairman

The subject of "Infantile Paralyses" was discussed from various specialistic standpoints Dr ROSA ENGELMANN opened the debate by first exhibiting a a porencephalic brain, obtained from a babe seven months old upon whom a craniectomy was performed by Dr Alexander Hugh Ferguson She showed photographs of the asymmetric head, site of the operation and pathologic intracranial cysts, as well as specimens of the brain, spinal cord and vertebral canal, from which the nerve exits and plexuses are demonstrated, for it was at first believed that these were absent, impossible as such a condition seemed The cord itself presented no cauda equinus and was undeveloped

Dr ENGELMANN then discussed the

CONTAGIOUS AND INFECTIOUS DISEASE ETIOLOGY OF INFANTILE PARALYSIS

That a relation between the infectious and contagious diseases to cerebral, spinal and terminal palsies does exist is undisputed, but what that relation is, is only explained in general terms No answer is given as to the reason of such comparatively uniform action upon nervous structures by such widely differing bacterial or noxious agents as syphilis, tuberculosis, smallpox, typhoid fever, scarlatina, purulent affections, pneumonia, measles, diphtheria, etc Why a poliomyelitis or neuritis should be a sequela to these diseases on the one hand, and, on the other, be an independent entity of a presumably specific origin, is inexplicable Of course, we recognize the immaturity and consequent instability of infantile nervous structures as a predisposing factor, but a wider and more accurate knowledge is dependent upon future neurologic research and accomplishment A discussion by the members of this Academy upon a history and specimen of a case of porencephalia in a babe seven months old may throw some light upon this evident congenital condition so often associated with cerebral palsies and acquired infantile cerebral palsies

The brain was obtained after a craniectomy done for me by Dr Ferguson There was a microcephalic state, as shown by the photographs, but I should have recognized other pathologic conditions and known of the uselessness of surgical interference □However, had no operation been done, no postmortem could have been obtained, and a valuable specimen and knowledge of great service to me would have been lost The history is as follows Parents Russian, father healthy, no history of nervous diseases, alcoholism or syphilis Maternal grandparent consumptive, mother undersized, with a pronounced dorso lumbar kypho scoliosis and rachitic pelvis Measurements made by Dr Rachel Yarros, as follows bi iliac, 21 c c, anterior superior spine, 20 c c, external conjugate, 11 c c, anterior conjugate, 9 c c The very prominent synchondrosis was found about two inches to the left Married at 20 Three children born at term and without difficulty, with the assistance of a midwife No miscarriages Two children died at the ages of four and eleven months respectively of pneumonia and summer complaint One living healthy child of 3½ years, subject to fright and hardships while carrying the youngest child, was sick in bed three months, complained of pain in the side, could not walk She also gives a description of sudden and copious white discharge, in the nature of a flooding, possibly the breaking of an abscess during this state Labor was prolonged and the physician told the husband it was a cross presentation Instrumental delivery Child asphyxiated for twenty minutes and to all appearances dead The father said the baby's left arm was broken, because the physician put it in a splint At the seventh month the child was brought to me, showing marked asymmetry of head with a deep left parietal depression, occipital depressions and elevations—in fact, great irregularities and absolute cranial synostosis Some facial asymmetry, but no observable facial or general paralysis History of convulsions since its second week, increasing in frequency and severity until almost constant, beginning with the ocular and facial muscles and becoming general Strabismus, blind and seemingly deaf, idiotic Perfect body development without other anomalies The child came to me with a history of cranial deformity from forceps injury, but upon noticing the synostosis, I said that the condition was congenital, and there was a conformation of the skull cap due to intra uterine pathologic cerebral conditions The operation and postmortem proved the correctness of this view On chiseling, the bone was found much hardened and thickened, especially at the sutures A cyst was noticed and thought to be hemorrhagic by the operator, but the child was so collapsed that the opening of it was left for a second operation The child died two hours after the operation The brain was removed, and I now present it to you for inspection The cord pulled up from the canal was at first thought to be without spinal nerves A postmortem was made later which demonstrated their presence The organs were found normal The only demonstrable pathologic condition was enlarged mesenteric glands, which looked tubercular There were adhesions of the coverings to the brain, and these and the cerebral tissue when fresh showed decided inflammatory changes, and pointed markedly to a fresh meningo encephalitis The sclerosis and atrophy were doubtless due to previous intra uterine lesions

---

[43] Rollett's *Traité des Maladies Vénérienne*

As to the cause, the question of pressure during pregnancy can be excluded by reason of the transverse position It does not seem plausible that labor or forceps pressure produced this condition of sclerosis and atrophy that must have been preceded by intra uterine acute inflammatory conditions of long standing, and due possibly to a pus infection in the mother previously mentioned, instead of developmental reversion The future may show that teratologic conditions have their origin in active fetal disease

Were there prenatal circulatory disturbances, hemorrhages or inflammatory disease of the middle cerebral artery, or obliteration early in fetal life, or an intra uterine polio encephalitis producing this terminal condition of sclerosis and atrophy? Was the synostosis due to the agenesis or vice versa? Ziegler inclines to the former view He says "In partial defects the skull cap is most often closed, giving rise to free spaces filled by fluid " Was this agenesis due to active intra uterine disease or to developmental arrest or perversions, or both?

SYPHILITIC ASPECT OF INFANTILE PARALYSIS

Dr Wm L Baum—The syphilographer is not frequently called upon to see cases of infantile paralysis When it is considered that between 75 and 80 per cent of the children suffering from hereditary syphilis are born dead, or die before the end of the third month, we can readily see how few cases of hereditary syphilis there are in comparison with the supposed number The lesions of the nervous system in these cases differ but slightly from those in the acquired type, and many of the so called pathognomonic signs of syphilis are not, strictly speaking, syphilitic manifestations, but symptoms of a dyscrasiæ which may differ widely from syphilis The specific lesions most frequently met with in infantile paralysis are most often confined to the cortical substance and meninges of the brain However, occasionally there are lesions occurring in the bony capsule which indirectly affect the nervous manifestations, and then the lesions also found in the medulla and cord The specific disease itself gives rise to congested conditions which are subsequently followed by atheromatous conditions of the cerebral arteries These are frequently followed by the development of smaller thrombi or miliary aneurysms The formation of these thrombi or aneurysms, especially the rupture of the latter, gives rise to various paralyses which are met with in children In those cases which are due to the formation of a thrombus the paralysis is gradual in its onset Where it is due to a rupture of a small miliary aneurysm, the paralysis is more sudden In both classes we have excellent results from treatment—rapid resorption and retrogressive changes to the normal In the cases, however, where there is a true sclerosis, also accompanied at times with the formation of a thrombus or rupture of a miliary aneurysm, there is softening and a true destruction of nerve tissue These cases show no improvement from treatment

The general practitioners and syphilographers are frequently misled into an erroneous diagnosis of the syphilitic origin of infantile paralysis upon the strength of the results obtained by therapeutic measures It is too frequently forgotten that iodids and mercurials are of great benefit in a great many diseases of non specific character and when these individuals recover as a result of the administration of these anti syphilitic remedies a diagnosis of syphilitic disease is made This is certainly a mistake, for if there are no other corroborative evidences of a syphiltic disease present, we are not justified in calling the symptoms, which may have a widely divergent origin, syphilitic

Fournier has reported a number of cases of syphilitic paralysis, in one of which there was enlargement of the lumbar vertebra, followed by paralysis of both legs This condition subsided rapidly upon the internal administration of anti syphilitic remedies While syphilis is an etiologic factor in infantile paralysis occupies an important place, care should be taken not to put too much reliance upon such a diagnosis without more apparent corroborative evidences of the disease being present

OBSTETRIC ASPECTS OF INFANTILE PARALYSIS

Dr C E Paddock—There are only two forms of paralytic affections occurring in childhood which are common one of these is known as spastic infantile paralysis and the other as infantile paralysis or essential paralysis of children, or scientifically as antero poliomyelitis One lesion is in the brain, the other is in the cord Of the cerebral palsy we have probably more to do in so called birth palsies Injury to the newborn during parturition with subsequent paralysis is more frequent than one is led to believe without referring to the literature upon the subject Rupture of a blood vessel in the brain or the meninges in a child results from different causes but in the obstetric sense by the application of some extraneous force A contracted pelvis, protracted labor, or instrumental delivery is equivalent to a traumatic injury to the skull and brain, that is, the result is the same, leading to a hemorrhage, usually into the meninges Protracted labor and not the forceps is the cause of greatest danger to the child's brain First born children are most apt to suffer, owing to the fact that first labors are, as a rule, harder and longer Gowers found that in twenty four cases of meningeal hemorrhage seventeen were first-born

The apoplexy of the newborn is, according to Osler, McNutt and others, one of the chief causes of the bilateral hemiplegia or paraplegia occurring at birth The fact that protracted labor is often the cause of paresis in the newborn is now generally acknowledged Whatever may be the cause of the delay the head is being compressed upon in all its circumference, the vessels become engorged and a rupture of some of the smaller vessels of the meninges necessarily follows with their consequent result What percentage of cases of paralysis in the newborn is the result of injury at birth I am unable to say, but I honestly believe that many cases which are referred to other causes are really birth palsies We have been taught in former days to delay the use of the forceps until such a time as danger is imminent to either mother or child, and here is where a great mistake has been made when the labor has been so protracted that the heart indicates impending asphyxia then, as rule, we are too late, for the child will either be born dead or born asphyxiated, resuscitated only to live a few days or a few weeks One should not wait until such a time has arrived, but be able to know just the proper time to apply the forceps, and this can only be accomplished, unfortunately, through a great amount of clinic experience The forceps is in the most skilled hand a dangerous instrument, but its dangers decrease with the skill which is acquired in its use A student goes out into the world to practice never having applied the instrument, and in his ignorance he does an incalculable amount of mischief The principal danger in the use of the forceps is in the high operations Thanks to Tarnier, we have the axis traction forceps which has reduced the terrors of a forceps operation to one of extreme simplicity The neglect in the treatment of breech presentation affords us many examples of infantile paralysis The traction which is often resorted to to terminate a breech results in an injury to the cord with the subsequent poliomyelitis Too much traction upon the over congested cord and compression upon the after coming head with hemorrhage at the base of the brain into the cavity of the arachnoid causes an effusion into the same cavity lower down, resulting in a spinal paralysis

What is the treatment of these conditions? A more thorough knowledge of obstetrics is necessary No branch of medicine requires such a thorough knowledge of medicine as obstetrics Emergencies are continually arising which call for prompt action Most any physician considers himself capable of conducting an obstetric case, and why? Because he has been taught that 96 per cent of the cases terminate favorably In this 96 per cent however, cases of infantile paresis are not considered that can often be traced to his negligence I have a fair idea of the operation for inguinal hernia, still I do not consider that I am justified in operating upon such a case neither do I consider that every man simply because he has an M D to his name is justified in conducting an obstetric case So soon as physicians realize t [illegible] trics is [illegible] that tracted labors are dangerous, that the forceps is an instrument of traction, not compression, so soon will the cases of infantile paresis due to mismanagement of obstetric cases be diminished

CLINICAL ASPECTS OF INFANTILE PARALYSIS

DR DANIEL R BROWER—The clinic aspects of the several forms of infantile paralysis are so familiar to every Fellow of this Academy, that I will not reiterate them on this occasion I have here a series of photographs which I think will supplement very well the admirable paper and specimens presented by Dr Engelmann These photographs are those of a family of infantile cerebral palsies The mother of these children is a very robust woman, who does her own work and takes care of these helpless children She is 31 years old and never had a miscarriage The parturitions of these several children were all normal The father is 49 years of age, thin and very anemic *He has been a painter since the age of 14*, has had no attacks of lead colic or other evidence of lead poisoning, has no history of syphilis, but has had numerous attacks of malarial fever, and has some stigmata of degeneration There are four children, all boys, three of them are diplegics, the other one is well with at least the ordinary intellectual and physical capacity of a boy of three and a half years The three children show the classical symptoms of mental defect—rigidity, contracture, exaggeration of reflexes and clonus, choreic and athetoid movements, and a slight amount of atrophy The oldest child is 10 years old The two photographs, one front and the other back view, show the characteristic attitude of the disease This child became diplegic at about two years The next child is 5½ years old and became diplegic about the same time The next child is 3½ years old and is well The youngest child was 15 months old when this picture was taken about one year ago, and has since become diplegic There has been no convulsion in any of the cases and the development of the paralytic symptoms has been gradual I am watching the cases with great interest, hoping after a while to be able to unravel the mystery that thus rendered helpless three out of four children, the offspring of parentage fully equal to the average of their station

EYE SYMPTOMS IN INFANTILE PARALYSIS

DR WM H WILDER—There are so many conditions of the brain in children that may give rise to paralysis of the muscles of the eye or to paralysis of the optic nerve, if I may so term it, that one can only touch upon them briefly I shall first speak of congenital defects of the muscles of the eye We are all familiar with cases of ptosis in children, but we are not so familiar with congenital paralysis of one of the extrinsic muscles of the eye A short time ago I presented such a case to the Chicago Medical Society, in which there was congenital paralysis of the external rectus The girl was 22 years of age There was no abductive power of the right eye, and this, according to the statements of the mother, had been the condition since birth Such cases are rather infrequent It can not be positively said however, that the paralysis is always due to some central lesion, such as defective growth of the nucleus We have just as much right to assume that it is due to defective development of the muscle Two cases are on record, reported by Seiler in which, on examination, he found absence of the superior rectus and the inferior oblique muscle of the right eye, and of the inferior oblique of the left eye In the second case there was absence of both oblique muscles in the right eye, and in the left eye absence of both oblique muscles and the superior rectus It is possible that the difficulty is due either to total absence or to defective development of the muscle However, in most cases of congenital ptosis that we see there is probably some defective growth of the nuclei in the fourth ventricle that innervate these muscles In other words, they should be considered nuclear palsies of congenital origin

When we come to acquired infantile paralyses we reach a large field Almost any disease that will bring about paralysis of the extrinsic or intrinsic muscles of the eye in adults may occasion it also in infants Trauma may be the cause of paralysis of any of the muscles of the eyeball either directly or because of a blood clot pressing upon some of the nerves A tumor in the orbit or immediately back of it would give a similar result

One of the most common causes of paralysis of the ocular muscles in children is either pachymeningitis or leptomeningitis, and naturally we should expect such paralyses to be more frequent with inflammations affecting the meninges of the base of the brain than with those confined to the convexity Consequently ocular paralysis is a common occurrence in tubercular meningitis, and may be one of the early signs of the same The child may show a pronounced squint, and if old enough may complain of diplopia This is not necessarily due to loss of power of any one muscle, but may be caused by a spastic contraction of one or more of them, a condition that may subsequently disappear Pressure upon the nerves either by tubercle masses or exudate may be accountable for this, although in some cases the cause must lie in a neuritis set up by the irritation The same cause may bring about partial or total loss of sight if the optic nerve become involved as it frequently does But the physician should be cautious about attaching too much importance to amblyopia in a case of suspected meningeal or brain disease, for such amblyopia may be congenital or caused by a high refractive error, and only to be detected by a careful ophthalmoscopic examination or some other objective test In children the chronic form of nuclear palsy of the ocular muscles is not so frequently seen as in adults, in whom syphilis so often acts to bring about the condition Dr Baum has correctly stated that congenital syphilis plays an insignificant rôle or no rôle at all in this disease Hutchinson in his famous memoir does not cite a case of congenital syphilis having caused paralysis of the eye muscles in children and his opinion is also held by Mauthner and other observers But closely allied to the nuclear palsy of adults is the condition described by Gowers by the name infantile oculo facial palsy To this class probably belong many of the cases of ptosis and paralysis of individual ocular muscles that are congenital or that appear in early life In this condition there will be associated with palsy of one or more muscles of the eye a paralysis of one of the facial muscles or jaw muscles There seems to be a peculiar connection in some persons between the center that innervates the levator palpebrarum and the center that innervates some of the muscles of the jaw Cases are not altogether infrequent in which patients having a ptosis are unable to raise the lid unless they make a corresponding effort to open the mouth It seems as if the impulse that is sent to the levator palpebrarum is, at the same time, sent to the depressors of the lower jaw This would seem to explain why in some cases of oculo facial paralysis we have a simultaneous or coincident paralysis of one of the maxillary muscles together with the muscles of the eyeball

It is singular that in conditions of intra cranial hemorrhage or spastic paraplegia of infants that we should not have more trouble on the part of the eye, because we have a blood clot in some cases pressing upon the convexity of the brain, sometimes reaching back and pressing upon the occipital lobe Gowers *mentions having seen but one case of complete blindness* in such condition Little mentions no eye symptoms in connection with it Unless a clot should be on the occipital lobes and press upon the sight center, we should hardly expect any manifestation on part of the eye We have in some febrile diseases serious disturbance of the ocular muscles In diphtheria we are all familiar with the paralysis of accommodation that occurs, usually following the paralysis of the muscles of the palate This may occur in connection with paralysis of some of the extrinsic ocular muscles For instance, a case was reported in 1885 by Uhthoff in *Neurologisches Centralblatt*, in which there was complete external as well as internal ophthalmoplegia, and a short time after Mendel reported one very similar In these cases we must suppose that some poison acts directly upon the centers in the fourth ventricle In Mendel's case, which went to autopsy, there was found considerable congestion around the nuclei of the nerves, the capillaries were much ingested, and there was a tendency to softening of some of the nerve centers

(To be continued)

PRACTICAL NOTES

Infection from Circumcision —The *Semaine Médicale* describes a case of tuberculous infection of the testes in an otherwise healthy child of healthy Jewish parents The infection was traced by a physician to the priest, who was found to be a confirmed consumptive, and who performed the rite of circumcision

The Use of Dry Heat of High Temperature in the Treatment of Chronic Joint Affections —Dr Wirt's apparatus consists of a copper drum twelve inches long and nine inches in diameter, fitted at each end with a wooden ring and a hood of thick rubber Having protected the back of the knee with cotton, it is enclosed in the apparatus and heat applied to the outside by means of a Bunsen burner Most patients will tolerate a temperature between 250 degrees and 300 degrees F , provided three holes were made in the drum to secure proper ventilation and keep the air dry This treatment gives an immediate relief to pain and increases temporarily the mobility of the joint.—*St Louis Med Journal*, October

Improved Method of Fastening Plaster Corsets —Gendron recommends the use of strips of zinc, one mm thick, three wide and as long as the corset Two are cut at intervals of two cm in oblong spaces across the strip, and the oblong piece cut out on three sides, but left connected by one of the small ends, and raised up like a trapdoor An unperforated strip is placed on the median line of the thorax and the layers of the plaster bandage applied On each side of this strip and at a distance of several centimeters the perforated strips are sunk in the plaster in the center of its thickness, the projecting raised pieces standing up out of the plaster After the corset is thus applied, the projecting pieces are bent down to form hooks, which enable the corset to be laced up firm and tight —*Semaine Méd* , September 30

Injection of Iodoform camphorated Salol in Chancrous Bubo — The *Gazette Méd de Liège*, October 1 describes the prompt cicatrization of eighteen cases of chancrous bubo treated by a French army surgeon with an injection into its depths of $^1/_3$ to $^2/_3$ Pravaz syringe of 1 5 per cent iodoform camphorated salol After the needle is withdrawn the hole should be stopped with the finger to prevent the escape of the fluid, and afterward painted with collodion The incision is postponed until the following day, when all the gelatinous pus is forced out by pressure A little mercurialized water at 1 to 1,000 helps to empty the pocket, which is then plugged with gauze dipped in the salol The pus is removed again the next day and a second plug inserted After this the bubo heals rapidly , the pain, swellings, etc , gradually disappear and the cicatrization proceeds regularly The fifth day collodion is applied and the cure is complete by the eighth day, leaving a scarcely visible scar with the skin loose

Diagnosis of the Possibility of Resuming Growth in Cases of Arrested Development —Dr Hertoghe of Antwerp, announces that growth can be resumed in all cases where the skeleton is not completely ossified, or as long as the bones retain their original cartilaginous character He has been studying three classes of arrested or delayed development Myxedema hyperazoturia and rachitis, simultaneously with the administration of thyroidin The most interesting part of his tests is that he diagnoses the cases first by means of radiography, which accurately determines the progress of ossification, and his diagnoses have been confirmed in every instance by the results of the treatment In myxedema the ossification is tardy, and patients with this disease resume therefore their growth upon the administration of thyroidin One of his cases was a young man of 27, who measured 1 37 meters in April, 1895, and has gained $1^1/_3$ inches (33 mm) since then, and is still growing The radiograph clearly showed in this case the distinct light zones in the phalanges revealing thus their incomplete ossification and the possibility of a resumption of growth in spite of his advanced age Cases of hyperazoturia also present a marked lack of ossification, and therefore are able to resume growing , but in rachitis, on the contrary, the bones ossify very early and no further growth is to be expected —*Semaine Méd* , September 30

Treatment of Yellow Fever —The editor of the *Tribuna Médica* of Rio de Janeiro, No 10, announces that he has found that the tincture of eucalyptus, administered promptly and in large quantities, has a marked effect in attenuating the severer symptoms of yellow fever He reports thirty one cases treated with it, and only three deaths, which were each probably due to the ignorant and careless attendance the cases received Very large doses can be borne as much as 30 to 40 grams in twenty four hours, with frequent enemas of 30 grams in a liter of water It seems to have an especially powerful effect on the kidneys, and prevents the usual anuria *O Brazil Médico* of August 1, also states that it has been the experience of Dr Costa, who has been at the head of a hospital in Brazil for twenty four years, that few if any cases of yellow fever were fatal that were accompanied by suppurated parotitis The suggestion is made that this might be produced artificially, and Fochier produces abscesses with turpentine, to prevent or modify purulent transformation of pneumonic exudates

The Dangers of the Operative Treatment of Enlarged Prostate — Dumstrey, in *Centralblatt fur Chirurgie*, records a case of enlarged prostate treated by ligature and resection of the vas deferens, which shows that this operation can not be regarded as a simple one and free from risk A man, aged 65, in all other respects strong and healthy, came under the author's care with complete urinary retention and severe cystitis due to considerable prostatic enlargement Partial resection of the vas deferens on both sides was followed in the course of a few days by decided relief of the local symptoms, the man being able to pass urine spontaneously and the urine becoming much less turbid and containing day by day less pus and blood The prostate, which just before the operation had been as large as a fist, was reduced in size by about one half These good results, however, were associated with serious impairment of both the physical strength and the mental condition of the patient He speedily presented the appearance of a very old and feeble person His movements became slow and clumsy, and he was unable to comprehend what was said to him and also to express his own thoughts After an interval of about a fortnight his condition commenced to improve, but the change for the better was very slow and gradual

Location of Foreign Bodies in the Eye with Roentgen Rays —Dr Clark, Columbus, reported at the recent meeting of the American Ophthalmological Society at New London, a case in which the presence of a small fragment of metal in the extreme angle of the anterior chamber and the iris where it could not be seen, had been determined by radiography The sensitive plate had been introduced into the adjoining nostril, the patient being put under ether, and the rays directed upon it through the eye from the temporal side He also suggested that the plate could be placed in the cocainized conjunctival sac, or an opening could be made in the conjunctiva and the small plate slipped behind it He believed that this method of locating a foreign body in the eyeball was perfectly practicable especially if the particle were lodged anteriorly, as in the ciliary region, where it could not be seen with the ophthalmoscope Dr Williams, Boston, reported a case in which a fragment of the copper case of a cartridge had passed through the cornea and lens Nothing could be seen of it and it was not certain that it was in the eye The use of the X rays showed the presence of the fragment, and it was removed The radiograph was obtained with ten minutes' exposure by laying the patient's head with the side of the injured eye upon the plate, and placing the Crookes' tube above and rather in front of the patient's head —*Ophthalmic Review*, August

Chronic Membranous Bronchitis —Clausse says that the nature of chronic membranous bronchitis has been but little studied, and gives the results of a bacteriologic examination of the membrane from a patient who had expectorated bronchial casts for several years Cultures showed an inconstant and small number of staphylococci and various forms of bacilli, but the only microörganisms found in abundance and in all tubes which did not prove sterile, were streptococci Cut sections showed the presence of various microbes on the surface of the false membrane, probably through contamination by the saliva, but in its center only streptococci were met with Fragments of introduced into the bronchi of animals or beneath their skin, produced practically no reaction, while inoculation experiments made with cultures of the germs were equally negative, yet, in spite of their lack of virulence, their constant presence shows that they were not a mere accidental coincidence, but that the disease was due to a chronic infection by them Anti streptococcic serum was tried with apparent success, the patient leaving the hospital in better condition than she had been for years —*Boston Med Journal*, October 8, from *Comp Rend Soc de Biologie*, April 3

Intra cervical Injection of Glycerin, a Modification of Pelzer's Method of Inducing Premature Labor —Helme improves on Pelzer's intra-uterine injections by introducing the nozzle of the syringe into the cervix alone, and describes with enthusiasm in the *Lancet* of October 3, the success of this treatment in two cases The important points are 1, that the intra cervical injection of glycerin produces a rapid and progressive dilatation of the cervical canal, 2, that at the same time the lower pole of the ovum becomes detached from the lower uterine segment, 3, that the intra uterine injection of glycerin between the detached portion of the membranes and the uterine wall may be carried out without fear of puncturing the membranes or of interfering with the placental attachment and 4, that labor is effectually induced As to the manner in which glycerin acts Pelzer offers the three following suggestions 1, it acts as a direct irritant of the uterine surface, setting up muscular contractions, 2, it acts through a mechanical separation of the membranes, and 3, its hygroscopic action causes a transudation of the liquor amnii, the ovum becomes smaller and is detached from the uterine wall, there is at the same time a contraction of the uterus upon its diminished contents But in addition to this power of setting up uterine contraction careful observation shows that glycerin possesses the power of causing dilatation of the cervical canal before contractions of the uterus, which are appreciable to the patient or the physician, are set up The injection of pure glycerin into the cervical canal is followed by immediate softening and relaxation of the cervical tissues with dilatation of the cervical canal, and this result seems to be too rapid to be the result of muscular action In one case of rachitic pelvis, four injections of 1 ½ ounces glycerin were made in eight hours with a fifth of three ounces the next morning Labor was shorter and recovery more rapid than ever before

Surgical Treatment of Tuberculosis of the Bladder — Greiffenhagen describes in the *D Zts f Chir* 3, a case of tumefaction of the bladder in a man of 47, whose urine contained blood and numerous Koch bacilli There was great pain and emaciation, with incontinence of the urine Clinical examination showed a tumor the size of a nut, a little above the symphysis pubis, which ascended or descended according to the quantity of urine in the bladder A similar tumor was situated also on the anterior surface of the bladder, and the external orifice of the urethra was also the seat of another, the size of a cherry There was also a hard swelling in the membranous part of the urethra The prostate was large but *not painful*, while the lower part of the bladder was intensely painful to pressure After several weeks of creosote medication—local treatment being impossible on account of the sensitiveness of the patient and the smallness of the urethra—a vast tumefaction formed in the perineal region, combined with complete retention of urine, which demanded surgical intervention After opening the abdomen on the median line, a multitude of small cavities were encountered, filled with a cheesy pus, and communicating with the urethra An opening was made into the fundus of the bladder and a large drainage tube inserted, after which the peri urethral abscesses were curetted out and iodoform gauze applied Five weeks after the operation the Koch bacilli had entirely disappeared from the urine A permanent catheter was introduced into the urethra after dilation The perineal wound healed, the tumors in the vesical wall and at the orifice of the urethra retroceded, and the general health continued to improve A year has passed since of perfect health for the patient, a farmer, who has pursued his usual occupations Greiffenhagen adds that such cases should more frequently be handed over to the surgeon, whenever instillations of sublimate and injections of iodoform fail to relieve —*Sem Méd*, September 30

Serum Diagnosis of Typhoid Fever —It has been shown by Pfeiffer of Berlin, and Widal of Paris, that the serum obtained from the blood of a patient suffering from typhoid fever is capable of so acting upon pure bouillon cultures of the typhoid bacillus mixed with it as to abolish the active motion characteristic of that organism in fluid culture media and cause an agglutination of the individual bacilli into large groups or clumps This change is easily recognizable under the microscope, or in culture tubes, and usually occurs within a few minutes It has since been shown by Dr Wyatt Johnston, bacteriologist of the Provincial Board of Health of Ontario, that the fluid obtained by moistening with water a dried blood drop gives the reaction in a prompt and satisfactory manner, even after it has been dried for several days This modification of the process makes it suitable for a system of free public laboratory diagnosis, similar to that in the case of diphtheria, as a drop of dried blood can be readily sent to a laboratory for examination Dr Johnston was able to diagnose the presence or absence of the disease correctly by means of dried blood drops sent by mail from Montreal, Canada, to Buffalo, N Y, during the recent meeting of the American Public Health Association To test the practical utility of the method the Board of Health of Ontario has issued a circular in which it offers to examine and report upon any samples of blood sent by physicians of the province The blood is to be taken from the finger tip or lobe of the ear, after thorough cleansing of the skin, by pricking with a needle previously sterilized by heating over a lamp or gas flame The drop is to be absorbed by a piece of sterilized paper which is furnished in an envelope by the board, with directions for its return A report is promised by 2 P M of the day following that on which the sample is received and will be communicated by telephone when the number is given By this systematic investigation the board wishes and expects to obtain data on, 1, the proportion of cases in which a correct diagnosis can be made by the serum test, and the relative efficiency of the method of employing dried samples, 2, the earliest period in typhoid fever at which this method can be expected to give indications, 3, the length of time for which it persists after convalescence, 4, the existence of any relation between the intensity of the reaction with the test and the course of the disease, 5, the study of the nature of the obscure febrile conditions, clinically termed gastric fever, continued fever, abortive typhoid, bilious fever, typho malarial fever, etc, about which our present knowledge is very meager and unsatisfactory The board is especially desirous of hearing promptly of and re examining any genuine typhoid cases in which the method is not successful In case of negative results, it is desired that after a few days an additional sample should also be sent consisting of a few drops of blood collected in a glass tube which will be furnished on application With reference to the effect of drying the samples it is observed that while this may lessen slightly the delicacy of the reaction it has the practical advantage of obviating a serious source of error, namely the contamination of the sample and the subsequent growth of putrefactive bacteria This is of special importance in the care of samples having to be sent long distances No doubt other boards of health will take up this subject and aid in the advance of our knowledge of typhoid fever and other febrile conditions

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE, INCLUDING POSTAGE

Per Annum in Advance $5 00
Single Copies 10 Cents

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 61 Market Street (Occidental Buildings) Chicago, Illinois

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association Dr Henry P Newman, Venetian Building Chicago Ill, sending him a certificate or statement that the applicant is in good standing in his own Society signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character intended for publication in the JOURNAL should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION 61 Market Street (Occidental Buildings) Chicago

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL

INFORMATION WANTED

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second class mail matter not having street address, would be placed in the general delivery to await call

SATURDAY OCTOBER 31, 1896

PHYSIOLOGIC TREATMENT OF NEURASTHENIA

Dr DAVID RIESMAN, of Philadelphia, closes up a well considered article on neurasthenia in the *University Medical Magazine*, September, by a scheme of treatment that embraces medicinal, hygienic and dietetic recommendations

1 Medicinal treatment can not be a matter of routine, but there are few remedies that are of benefit in a large number of cases

At the head stand the bromids, of which he generally employs the sodium or potassium salt in doses of fifteen grains two or three times a day, strontium bromid, in thirty grain doses, has also given good results, particularly in lithemic cases

The coal tar products, either alone or combined with the bromids, are often of value A remedy, for which much has been claimed but which he has not used, is spermin The animal extracts have been employed, but it is questionable whether the results achieved are not due to suggestion

Special conditions will naturally demand a modification of our treatment Insomnia needs often to be combated, frequently a hot sponge-bath before retiring, or the application of hot towels to the face, is sufficient to encourage sleep When drugs must be employed, we resort to bromids, sulphonal trional or hyoscin, never, if possible, to morphin Marked lithemic conditions are corrected by the use of alkaline mineral waters, the lithia salts, or by piperazin and its congeners

In nervous dyspepsia, in addition to regulation of diet, suitable remedies may be administered The mineral acids are of value in some cases, antiseptics and sedatives, such as bismuth subgallate, in others The constipation is treated by the customary methods

2 Dietetics —The diet in neurasthenia should be nutritious, it has no special limitations except when the rest-cure is employed or when distinct indications are present The patient's idiosyncrasies must be considered If anemia exists beef, eggs and milk are given in abundance, in lithemic cases the meats are restricted, and alcoholic beverages as well as rich articles of food are excluded from the dietary

For nearly all cases coffee and tea seem to be harmful, and he has been in the habit, perhaps with too strict an adherence to routine, of always forbidding their use

If symptoms of nervous dyspepsia are present, the sugars and starches should be as much as possible eliminated from the diet, the patients often do well when placed on rare meat, stale bread or gluten bread and milk Milk is especially valuable in cases suffering from gastralgic attacks

3 Among hygienic measures the most important is rest, prolonged rest is to the neurasthenic patient what the nightly sleep is to the healthy man In severe cases it is necessary to adopt the so called rest cure, or Weir Mitchell treatment, consisting of rest in bed, massage, electricity and liberal feeding This may bring about a cure in an apparently hopeless case During the rest cure the patient is not permitted to see his or her friends, is not allowed to read, and is in constant charge of an intelligent, strong-minded nurse

As important as any of the measures adopted, indeed, deserving to be ranked the foremost factor in treatment, is the personality of the physician In no disease is it so essential to inspire the patient with confidence, and in none is so much good accomplished by suggestion alone as in neurasthenia The physician should listen patiently to the almost interminable recital of fanciful ailments, and should always make a careful physical examination to exclude all possibility of lurking organic disease

If the rest-cure is impossible or not indicated, the patient must take a definite amount of rest by lying down for an hour or two in the morning and in the afternoon—this is especially valuable in women

Bathing is not to be neglected The bath should be of short duration and should be followed by a cold shower bath or cold douche, with friction In the so-called sexual neurasthenia, the application of cold water to the spine and the perineum acts as a powerful sedative

A change of climate, such as a sojourn at the seashore, in a retired spot, or a sea voyage of some length, is valuable in many instances

In neurasthenia with disturbances of the sexual functions a combination of bromids and hyoscin is very useful The patient should also be instructed to sleep on his side (this may be accomplished by having him bind a cigar box on the back, or by tying a towel about the waist with the knot behind), and to apply cold douches to the spine and perineum For this class of cases outdoor exercise is very valuable

WATER SUPPLY OF DENVER AND CHICAGO

An increase of typhoid fever deaths in the city of Denver, amounting to nearly 35 per cent in September last over the average for the previous three months as compared with the usual seasonal increase of less than 12 per cent, has been made the occasion of an exhaustive study of the water supply of that city by its accomplished commissioner of health, Dr William P Munn His preliminary report to Mayor McMurray on "The pollution of certain sources of the water supply of the city," and his comments thereon, will be a revelation to other commissioners of health and to other mayors of cities

Dr Munn seriously proposes that the water from all sources of the Denver water supply shall be pure and healthful, even if it be necessary that they be passed through "properly constructed and efficient filters, which shall give an effluent having an average at all times of less than 100 germs per cubic centimeter," and that "if any of the patented processes are adopted for the removal of impurities by mechanical or chemical methods, it shall be a condition that a month's test shall show an effluent at all times containing less than 100 bacteria per cubic centimeter, and that the test shall be carried on with the waters of the proposed supply, and that the proposed filter shall be approved by the mayor and the health commissioner, and the tests supervised and accepted by them as satisfactory "

There are communities far more pretentious than Denver—one of them has the honor of being the home office of the Journal—where the permissible limit of the bacteria is ten times this number, and where the records show more than seventy times this number as an actual average

In his report Dr Munn shows, as has been shown by others, that typhoid fever prevalence follows the pollution of the water supply, that it subsides with the improvement of the supply, and that "the great bulk of cases of typhoid fever in all epidemics is due to the one common cause—an infected water supply " He adds "When the probable sources of that infection are discovered, it is the plain duty of those upon whom the responsibility lies to suggest the remedies Failure to adopt the remedial measures that are necessary means deliberate acceptance of responsibility for the resultant loss of human life "

The Journal begs to commend this utterance, which will be endorsed by every sanitarian in the country, to the prayerful consideration of the civic and educational authorities of the city of Chicago, where the death rate from typhoid fever is again becoming the highest in the world

TABLET MEDICATION

The "tablet fad," as some of our pharmaceutic friends choose to call it, appears to have come to stay. The convenience, cleanliness and presumably accurate dosage of the preparations recommend them readily to the practitioner, and at the present time there is hardly a doctor's office where the familiar glass stoppered bottles and labels of the different manufacturers are not to be encountered They have undoubtedly affected the druggists' business to some extent, and have perhaps also modified medical practice, how materially is a question to be settled in the future That they are the unmitigated evil that some pharmaceutic writers hold, is doubtful, but that their extensive adoption as a mode of drug-dispensing by physicians has in it possibilities to be deprecated, is pretty nearly certain In their present development, it may easily happen that with some they may induce an indolent or careless therapeutic method—that ready made shotgun prescriptions may become popular and an actual evil It is easy also to see how, without any standard authority regulating these preparations, there may be some among them that are not only useless but absolutely dangerous combinations introduced to manufacturers and sent out among the profession It may be there are none as yet of this kind that are really of any importance, but we have to reckon with their possibility Certainly there are some among them that are ineffective or uncertain

All the objections to these tablets could, it would seem, be avoided if there were a standard list, made up mainly of simple drugs, a few well tried or rational combinations perhaps included, which could be prescribed if so desired and supplied by every druggist, and which could be combined according to the needs of any special prescription if the physician desired to dispense his own medicine A very large proportion of the pharmacopeia is made up of substances that can very readily be made up into these tablets, the convenience of which is now being daily demonstrated Others that are not thus suitable, but which are now included in the manufacturers' lists, would of course be omitted from the standard list and it would in this way save both physician and patient from being misled into trouble and expense The addition of a class of compressed tablets and tablet triturates to the regular pharmacopeia would not hurt any business more than is being done at present and would regulate what is at present a somewhat irregular, but widespread and popular method of medication and one that has its real advantages and merits

THE NEW YORK STATE MEDICAL ASSOCIATION

Thirteen years ago the New York State Medical Society separated on the code question. Those who believed in the code of the National Society began to hold their annual meetings in New York City, and were designated as the New York State Medical Association. The State was divided into five districts, presided over by vice-presidents, and holding quarterly and semi annual meetings. The regular annual meeting of the Association, at the Mott Memorial Hall, New York City, was held October 13, 14 and 15, and was of more than usual interest. The President's address on "Medical Expert Testimony," was a suggestive, thoughtful study of the subject by Dr. Darwin Colvin of Clyde, N. Y., one of the few living original members of the American Medical Association. Dr. Austin Flint of New York in a special report on criminology dwelt on the injustice of the law forced through the legislature by the labor unions, taking all contract labor from the prisons, leaving the prisoners in idleness and increasing the cost to the State. A symposium on prostatic enlargement and its surgical and medical treatment brought out a very interesting discussion. Among the large number of important papers was one by Dr. E. D. Ferguson, on "Fatal Cases Presumably Due to Intestinal Ptomains," which gave a new meaning to a class of obscure symptoms, and suggested a new field of study that promises brilliant discoveries in the near future. The address on surgery by Dr. Phelps of New York City, was an exceptionally clear philosophic critique of the general progress of surgery and medicine, also a plea for higher ideals of professional life and living. Dr. Sayre's paper "On the Practical Uses of Roentgen's Discovery as Applied to Surgery," illustrated, was of great interest. The program as a whole was very significant of a great evolution in the practice of medicine. Of the forty-five papers and addresses offered, over thirty were devoted to surgery. Many of them were reports and discussions of very formidable operations, mostly by physicians living away from the large cities and centers of learning and doing a general practice.

The post graduate schools are clearly doing a revolutionary work in preparing the general practitioner for surgical operations which were formerly only done by leaders in the profession and at large hospitals. Evidently a decided evolution is building up surgeons in inland towns and villages, competent for ordinary demands of modern surgery. This however, may go too far, as that manual dexterity resulting from daily practice required in certain exceptional operations can only be acquired in the large hospitals. While undoubtedly surgery is one of the fascinating branches of modern medicine, and at present outranks all others in prominence, yet the topics of papers seen in programs of medical meetings, indicate many and probably far more important fields of study. The New York State Medical Association is one of the prominent Eastern societies, whose membership includes many of the leading medical men of the country and whose published transactions are eagerly sought after as representing the advanced studies of medicine.

Yet all medical societies' meetings suffer from the inability of readers of papers to condense and give the listeners the conclusions of their studies only. In an annual meeting of several days duration, outside the addresses on general and special topics, the readers of papers should be limited to conclusions and summaries of their arguments, leaving to the printed page the facts and observations which can be studied at leisure. Often readers of good papers fail to rouse up any interest by faults of tone and address. Many authors appear at their best in print, and should never read their productions. Others are best in impromptu debate and exchange of opinion.

The model medical meeting is yet to come but there are signs of its near approach every year.

THE COOK COUNTY (ILLINOIS) HOSPITAL

The Practitioners' Club of Chicago held a meeting Monday night, under the presidency of Prof. Christian Fenger, at which they discussed the perennial Cook County Hospital question. The speakers were Drs. Steele, Babcock, T. A. Davis, Senn, W. T. Montgomery, Brower, Hamilton, Moyer, Lewis and Wilder. Some curious facts were brought out in the discussion, among others that the members of the staff, with very few exceptions, were the private physicians of the county commissioners, and that the price of appointment was free treatment of the special commissioner and his family, together with the political pull of the incumbent. One of the speakers stated that internes at that institution were in the habit of performing capital operations in emergency cases without waiting for an attending member of the staff, and that they did not hesitate to perform such dangerous operations as amputation of the hip joint. Statement was made that no provision for bedside instruction was at present made at the hospital, and that it was optional with the patients whether or not they were admitted to the clinic amphitheater. One of the members of the staff, while speaking in a manner entirely friendly to the management, asserted that cases of phthisis pulmonalis, even in an advanced stage, were frequently placed in beds alongside of cases of typhoid fever, pneumonia or bronchitis and that no separation of these cases was even attempted, that the temperature of the wards was very badly managed, and as a rule kept entirely too high, and remonstrances on the part of the staff were of no particular avail, as the institution is under the management of a lay "Warden," responsible alone to the county commissioners.

These defects in the largest hospital of Chicago are not creditable to the public, and the necessity for putting the hospital under medical rather than lay supervision has again been demonstrated

At the same meeting a motion to recommend the commissioners to abolish the hospital ticket fee for students was voted down on the statement of Dr T A Davis that this money was used for laboratory purposes Resolution was finally passed inviting the cooperation of the Chicago Medical and other regular societies of the city, to take immediate action this week, *before the election*, recommending that hereafter the regular members of the hospital staff be appointed on the recommendation of the Chicago Medical Society

GETTING RICH "BY DEGREES" IN ITALY

The Rome correspondent of the London *Lancet*, September 19, records the fact that three years ago the sale of bogus degrees had reached proportions in Bologna which incurred the intervention of the police, and their manufacturer is still, it is believed, serving his time in one of the local prisons But the summary example made of him has not, it would appear, proved much of a deterrent At least, from information gathered in Italy the industry is still a paying one, if the number of graduates whose scholastic record is rather dim may be received as a test This time the University which confers the diplomas is not Bologna, but Berne, whose *sigillum magnum* was stolen, or in some way got at, so as to be counterfeited to perfection The alleged thief or forger has been arrested, but the article was not found in his possession and is still to seek So the world is not yet safe against the illicit creation of graduates, medical and other, but chiefly medical, of whom, it seems, there are already nearly three hundred vaunting themselves alumni of the leading Swiss University Scandinavia and Germany boast the majority of such graduates, while there are some fifty or so practicing in or on the English-speaking public in both hemispheres The rest are chiefly to be found in Italy, Austria and the East

CORRESPONDENCE

Glandular Interdependence

Chicago, Sept 25, 1896

To the Editor —In an editorial on "The Vital and Psychic Complications in Castration for Prostatic Hypertrophy" which appeared in the Journal of Saturday September 19, the writer in speaking of the testicles, observes "that these organs are absolutely without function at an advanced age is most certainly untrue for many individuals There is probably a germ of truth in the theory of Brown Séquard as to the invigorating influence of the testicular secretion, certainly the experimenters in organo therapy have not lost faith in it altogether The organs do not atrophy completely even after their special sexual function has apparently long been lost, and it is only reasonable to assume that they still have some utility in the organism " This is perfectly true I think we may safely infer that no organ of the body performs but one function and that alone The several tissues, using lymph as a medium live upon the blood, taking up from the blood the materials for, and returning to the blood the products of, their metabolism Therefore, the supply of blood that is not only deficient in quantity but defective in quality is one of the causes of nutritive derangement And another cause is the failure of the organism to eliminate the waste products which accumulate in the blood But yet a third cause of defective nutrition is the alteration of the blood which consists in the interdependence of each and every tissue of the body upon one another, and hence no part can either be removed or remain inactive without producing an ill effect upon the rest of the body Foster expresses himself on this subject in the following words "Changes in one organ may affect the condition of other distant organs by changes induced in the composition or qualities of the blood " And again "The products of the metabolism of one organ are carried to other organs for further elaboration and possible utilization " Take, for instance, the liver We know from Minkowski's experiments on birds, and from the experiments of Hahn, Masson, Pawlow, Nencki and others, on dogs that the extirpation of the liver in the former is attended with the replacement of uric acid by ammonia and lactic acid, and the ligation of the hepatic artery in the latter replaced uric acid by the carbonate of ammonia These experiments go to show that the liver protects the organism from poisoning by the products of its own cellular activity And Bouchard has demonstrated that this function of the liver diminishes in an enormous degree the toxicity of the waste products

Take next the pancreas It has been conclusively proved by the experiments of Von Mering, Minkowski, Lancereaux, Gley and others that besides its digestive functions the pancreas subserves the important purpose of utilizing the glucose that is normally present in the blood Extirpate the organ or tie all its veins and we have glycosuria or pancreatic diabetes as an immediate result Forty years ago Schiff demonstrated the troubles and alterations of nutrition following the extirpation of the thyroid He then believed that this body elaborated something which had an important effect on the nutrition of the nervous system This has since been verified classically in myxedema

From Gley's experiments on the rabbit we come to find now that acromegaly, that peculiar hypertrophy, is associated with disease of the pituitary body From the studies of Addison and the experiments of Brown Séquard, Langlois, and recently of Schaefer and Oliver, we have arrived at the conclusion that the medullary portion of the suprarenal capsules secretes something which increases the tone of all muscular tissue, especially of the heart and arteries Indeed, even the kidneys perform other functions besides that of eliminating waste products Bradford's experiments conclusively demonstrate the fact that the renal organs possess and perform another function, viz , the metabolism of the tissues

It is more than probable, therefore, that the testicles also have functions besides those intended for procreative purposes Testicular preparations may, therefore, reasonably be assumed to possess useful properties That they actually do influence the general nutrition will be readily admitted by the results obtained in the following case

L M , age 62, an Englishman by birth, has for thirty eight years been a sufferer from psoriasis When examined in June, 1896, was found to be pretty nearly hide bound by a thick layer of silvery scales from his head, forehead and neck, down his front and back, his arms, nates and legs to the palms of his hands and soles of his feet His nails looked "worm eaten," and the bends of his elbows and knees were cracked and bleeding In his travels in Europe he had consulted every dermatologist of any name and had tried every known remedy recommended by Startin, Tilbury Fox, Hebra, Unna, Kaposi and others He had tried hydropathic treatment for two years every description of sulphur treatment from simple sulphur to all kinds of sulphur preparations, including ichthyol and resorcin, with sulphur and mud baths for another two years, had been pitched and tarred within and without for another two years, the thrysophanic acid, chrysarobin, anarobin, mercury, iodin, pilocarpin and arsenic treatments for yet another two years, hot vapor baths, pure and medicated with salicylates, colchicum, potash soda and lithia, with all manner of diaphoretics, diuretics and purgatives for an indefinite period But it was of no use, the disease persisted and latterly he had ceased all treatment and was resigned to the inevitable

He was given a bottle of phospho albumin, a very palatable testicular preparation, made in Chicago, and he was advised to discontinue all external applications, and to avoid the use of water He *took a tablespoonful three times a day after each* meal, and he felt encouraged to continue the treatment until he had taken three bottles of it, when he was again examined

Now it was approximately estimated that this skin trouble covered about 2½ square feet of the surface of his body and I have to report the remarkable fact that after taking his third bottle of phospho albumin there was not a speck of the psoriasis to be seen Over the diseased patches were now visible dark chocolate brown stains, but of perfectly velvety smoothness without the least irritation or pruritus This is not the first or only case of psoriasis cured by testicular preparations Bouffe reports good results from Brown Séquard's fluid in this obstinate disease (*Press Med Belge*, 1894, No 35) I have another case of seventeen years' standing now under this treatment, but not enough time has yet elapsed to allow of any opinion being expressed as to its effects It is just possible this treatment may not succeed in the next case, for we do not know what the something is that produced the results and, hence, we are as yet ignorant as to the exact indications for its use In the next place we are ignorant of the causes which produce psoriasis When found in conjunction with syphilis specific treatment is beneficial, when it flourishes on a rheumatic or gouty soil the salicylates, colchicum and alkalies help to alleviate the urgency of the symptoms, but when it is "idiopathic" (a term which expresses our ignorance of etiology) and seems to be nothing more or less than a surface manifestation of some general nutritive derangement, then phospho albumin gives results that are simply marvelous The glandular bodies should be studied in the laboratory as to their physiologic chemistry and histology, and these studies combined with experimental physiology and empirical therapeutics might lead to great revelations M H LACKERSTEEN, M D

The Proposed Leprosy Congress

NEW YORK, Oct 19, 1896

To the Editor —I enclose some copies of letters relating to the proposed leprosy congress The first idea was to hold it in Bergen, Norway, out of compliment to Hansen The latter has now renounced his personal claims, and the opinions are now divided between London and Moscow As you will see, we were happy enough to secure the interest of Queen Victoria, and we have a well grounded hope that the British government will take an active part in the enterprise Dr Hutchinson thinks that the Prince of Wales will almost to a certainty consent to act as president of the Congress if held in London As the British empire is more interested than any other country in the question of leprosy, it seems but natural, especially with these great advantages, that London should be chosen Dr Morrow who is the committee appointed by the American Dermatological Association to represent it in the matter of the Congress, and who was given full powers to act, votes for Bergen first, London second, as the seat of the Congress and thinks that the most successful meeting could be obtained for London if our Congress meets shortly before or after the Moscow General Congress I myself shall vote for London Will you kindly favor us with an editorial voicing these sentiments, and greatly oblige, Very truly yours,

ALBERT S ASHMEAD, M D

LONDON, Sept 22, 1896

Dr ALBERT ASHMEAD —*Dear Sir* At the Ambassador's request I have much pleasure in enclosing herewith the answer from Sir Arthur Bigge to your letter addressed to the Queen I am, dear sir, your obedient servant,

JOHN RIDGELY CARTER, Secretary to U S Ambassador

BALMORAL CASTLE, Sept 21 1896

Dr ALBERT ASHMEAD —*Dear Sir* In reply to your letter addressed to the Queen and forwarded through the embassy of the United States in London, I have the honor to inform you that your communication has been duly laid before Her Majesty, who is interested in hearing of the proposed International Congress for the suppression and prevention of leprosy Your letter has now been forwarded to the Queen's ministers, in order that the question may be considered and dealt with by those who in all such matters must be Her Majesty's responsible advisers I have the honor to be, dear sir, yours very faithfully,

ARTHUR BIGGE, Private Secretary to the Queen

LONDON, Sept 16, 1896

Dr ALBERT S ASHMEAD —*My Dear Sir* I warmly approve your scheme and vote with both hands for Bergen It would be a mistake to make it a part of the Moscow congress If in Bergen and well ahead of the Moscow meeting, so that those who wished could attend both, it would, I think, be well attended For myself I might hope to get to Bergen, but scarcely to Moscow

I do not think that I much approve the idea of collecting money for leper houses What we have as medical and scientific men to do is to find out the cause and the means of prevention, and we should need all the money we can obtain for researches In the administration of the "Prince of Wales fund" we felt it to be a mistake to have undertaken aid to asylums It wasted our funds and did an infinitesimal amount of good

If you thought well to compromise and meet in London, I do not doubt that the Prince of Wales would consent to be president If you appoint patrons he would probably give his name to the Bergen list

Why not include "Yaws," or why not make it "For the Study of widely spread Endemic Diseases, Especially Leprosy and Yaws" It might still take its colloquial name from leprosy Wishing you success, I am, yours sincerely,

JONATHAN HUTCHINSON

TOKYO, JAPAN, Sept 2, 1896

Dr ASHMEAD —*My Dear Doctor* I am directed to acknowledge with thanks the receipt of your favor dated New York, Aug 5, 1896, and beg leave to reply that Prof *Kitasato* is highly delighted to hear of your project, and that he will be glad to do all in his power to further the interests of the Congress He is making researches on the subject you mention, and if they are completed at the time the Congress meets it will afford him much pleasure to report them He sends his best regards Yours very truly,

A NAKAGAWA, M D

Assistant in Institut fur Infections Krankheiten

BOGOTA, COLUMBIA, Sept 12, 1896

Dr ALBERT S ASHMEAD —*Dear Sir* I have had the honor to receive your favor of August 5 of this year, in which you do me the honor to inform me that in the coming year there will be held in Bergen a Congress of Leprologists, to which you do me the honorable distinction to invite me, and at the same time my own interest prompts me to interest myself with the government of my own country to make it accept the invitation which you address to that government, to take its place in the said congress, and to send to it an official delegate As for me, I accept with the greatest of pleasure my dear sir, such a signal show of appreciation, and I shall take my place in the Congress unless some u [illegible] accident prevents me Should such an accident [illegible] may be s[illegible]re of the sero the [illegible] you des[illegible] [illegible]ads in m h[illegible] receiv[illegible] o historic information, and a lot of things which seem to me to interest the eminent leprologists who will meet at the Congress

Since I have received your letter I have addressed myself to the Minister of Foreign Relations, in order to satisfy the recommendation made by you, and he told me that he had not yet received the communication which you declare having sent him through the American Minister But he thinks that he may assure you that the government will accept the invitation and that it will send an official commissioner, as you have asked him

And now will you allow me to ask you one question? I should like to know that Dr Hansen will experiment on some case of leprosy of the Hospital Luugaarde with serum therapy treatment which a year ago I have tried here, with good result, in order that when the Congress of Bergen shall meet the distinguished scholar will be able to pronounce his idea according to that treatment For that effect, I remit to you some copies of my third communication to the Academy of Bogota in which there are to be found all the details necessary to the propagation of the anti leprous serum, and for the treatment of the patients by that method Hoping for the kindness of yourself that you will forward this paper to Dr Hansen If he wants to make the experiments, without taking to himself the trouble of making the serum, you will do me the favor to let me know, that I could send from here the serum which will be necessary for him

With the feeling of the most distinguished considerations, I have the honor to declare myself your most attentive and sure servitor, JUAN DE DIOS CARRASQUILLA, L

COPENHAGEN, Sept 18, 1896

Dr ALBERT ASHMEAD —*Dear Sir* I have had great pleasure in receiving to day your letter, because I am working on the same subject since last year At the last congress in London in August, 1896 I spoke with the most renowned European leprologists of this matter, and they were all together of the unanimous opinion that a league against leprosy ought to be formed like the leagues already existing against tuberculosis and cancer I am going to Berlin one of the first days of October to find several other leprologists of our union I shall inform you of our deliberations on my return

Yours very truly, DR EHLERS

Treatment of Diphtheria

CAMDEN, N J , Oct 19, 1896

To the Editor —In the formula of my antiseptic solution in the JOURNAL, Oct 17, 1896, just to hand, an important misprint has occurred It should be in the formula *five* drops of carbolic acid instead of one drop

Will you kindly and promptly correct the same in your next issue Also I send you two letters which are of great interest in connection with my method of treating diphtheria Please give them space Yours very sincerely,

D BENJAMIN, M D

CAMDEN N J , July 16, 1896

Dr D BENJAMIN, *My Dear Doctor* —In reference to your Antiseptic Treatment for Diphtheria, will say that I have used your treatment for the past three years in at least seventy five cases of true diphtheria, without a death

The membrane disappeared so quickly in certain cases that reporting the case to the board of health seemed unnecessary

In a case of a little girl on South Fourth Street, Camden, who was taken with malignant diphtheria, her brother having died only a few days previous, in the hands of another physician, it was my privilege of witnessing the efficacy of this antiseptic treatment

The membrane disappeared in less than thirty six hours, the little patient convalescing on the fourth day As long as the above treatment gives me this percentage of cures, I have no need for antitoxin I remain, fraternally,

WM J KELCHNER, M D

CAMDEN, N J , July 9, 1896

To the Editor —Learning that Dr Benjamin is going to publish an interesting case of diphtheria, and seeing the case with him I desire to make the following statement

During the practice of twenty one years I have naturally met with a large number of cases of diphtheria , but the most malignant case that I ever saw to fully recover was Mrs Samuel Mills, of 726 Clinton Street, this city, who had two children die in close succession from diphtheria, who had been attended by a homeopathic physician Some time in April last, while attending the funeral of her last child that died, she was suddenly taken with a severe chill, and complained of a painful sensation in the throat, with intense pain in head and back She was quickly driven home and Dr Benjamin sent for Her condition became rapidly worse and her symptoms so alarming that her husband called at my office and requested me to take charge of the case until Dr Benjamin arrived

Under the circumstances I consented to do so I just had time to examine the patient, however, when the doctor drove up He confirmed my diagnosis that it was not only a typical case of diphtheria, but a most malignant form of the disease Upon examination he found her temperature to be 105, pulse 130, and respiration 26

I saw at once that it was a case calling for the antitoxin treatment Had she been my patient and had I been alone, I probably would have resorted to that remedy , and then Dr Benjamin declared in the face of such an unfavorable prognosis, that he not only would cure the case, but would in a very few hours check the progress of the disease by employing two well tried remedies of his, both locally and internally , I must acknowledge that when he made that statement I became somewhat incredulous But nevertheless the doctor evidently knew whereof he spoke, as in a remarkably short time, under the antiseptic treatment employed directly to the throat (which he claims destroys the germs and microbes at once), the patient showed marked symptoms of improvement The temperature soon became normal, the diphtheritic patches soon cleared off, and in less than a week the patient was down stairs

Respectfully,

217 South Sixth Street E E DEGROFFT, M D

Drinking Waters for Travelers

NEW YORK, Oct 16, 1896

To the Editor —We regret to encroach upon your time and we hope you will pardon us for doing so as a result of our desire to have you favor us by correcting in the JOURNAL an error which inadvertently crept into the issue of September 19 page 664, where, speaking of the several drinking waters for travelers, it is made to appear that Apollinaris Water and the various Hunyadi Waters are aerated drinking waters of the same standing

While it is true that Apollinaris is a dietetic and table water which the profession have time and again recommended to travelers in districts where the drinking water is the subject of suspicion, on the other hand the numerous Hungarian Bitter Waters coming from Buda Pest, which are called Hunyadi this or that, are strictly medicinal, being aperients, and, if reports go for anything, vary much from time to time in their specific gravity, in consequence of which Professor Liebreich (University of Berlin) in an article published in the *Therapeutische Monatshefte*, said

"It is, therefore, a matter for high satisfaction that the aperient water 'Apenta,' from the Uj Hunyadi Springs in Ofen, has been placed under state control The Royal Hungarian Chemical State Institute (Ministry of Agriculture) has undertaken this charge and, therefore, it is now possible to obtain a water which is free from injurious extraneous waters infected with organic substances The analysis has been published by Professor Liebermann, Director of the said Institute The proportion of sulphate of soda to sulphate of magnesia is 15 432 to 24 4968 in the liter, so that this water is to be classed with the best aperient waters, and may be pronounced one of the strongest Owing to the constancy of the Apenta Water ensured by the state guarantee, that confidence in aperient waters, which had been lost, will be revived in favor of this important therapeutic agent"

As an error in the columns of a journal of such high standing and authority as yours is apt to confuse many readers to their disadvantage and ours, we trust that you will be good enough to give the matter attention Yours very truly,

CHARLES GRAEF & Co

He Likes our Journal, but Money is Scarce

MILLBORO SPRINGS, VA , Sept 6, 1896

To the Editor —I received your letter and the JOURNAL September 25, please accept my thanks for them both After awhile (D V), I will become a member of the AMERICAN MEDICAL ASSOCIATION when money gets less ridiculously scarce

There is no money in rural sections now Corn 15c per bushel, butter 12c per pound, sweet potatoes $1 00 in July last, when a few years back they were $7 00 per barrel Nothing that a farmer has will sell

Send me the JOURNAL semi occasionally I enjoy the editorials, the terse and brilliant dash of the versatile pen tends to reason like the "needle to the pole," making their conclusions "solid buildings," no "castles in the air"

I am like you, doctor, about that terminology of "fair culture" We were all taught in about the first lesson in our Latin grammar that "os" and "on" were Greek terminations As to "stomatomycosis" and "coprostasis," "fair culture" slipped like "Cæsar in Africa," unlike him, however, I am sure he will not hold his "tripper," or wish to, when he looks for the words *κόπρος* and *στάσις*, nor will he find lead poisoning, whatever other morbific (escaping) elementaries there may be afloat This is strictly between you and me I am no critic, neither wish to be In your position you are compelled to notice such blunders

I will join the ASSOCIATION, nothing happening to prevent it, some time I am sincerely, etc ,

W S S

Twelfth International Congress of Medicine

MOSCOW, RUSSIA, Oct 10, 1896

To the Editor —Will you kindly insert in an early issue of your esteemed journal the following notice

From the Surgical Section of the Twelfth International Medical Congress in Moscow —Acting upon the advice of Dr E Browitz (Konigsberg), the Surgical Section of the Twelfth International Medical Congress has decided, in view of the approaching Congress, to collect international statistics on narcotizations for the current year (1896) For this purpose the managers of the said Section apply to all their colleagues and earnestly request them to give answers to the following questions

1 Number of narcoses from Jan 1, 1896, to Jan 1, 1897?

2 What narcotics were administered?

3 Number of fatal cases?

The Secretary of the Surgical Section, F Rein, Malaja Dmitrowka, house Scheschkov, Moscow, Russia, will be glad to receive such information, and, if possible, not later than July 1, 1897

F REIN, M D , Secretary of the Surgical Section

Serum-therapy

CHICAGO, Oct 25, 1896

To the Editor —Lahmann's assertion (see "Serum therapy," JOURNAL, No 17, page 914), upon healing diphtheria by freeing the body of autotoxins reminds us of the old therapy of evacuating the toxins by moving the bowels and sweating an old plan, with right relinquished or left to the quacks The renewal of the idea with some physiologic rays makes it no more valuable, we should be on our guard, having enough of the sort in the country

KL

Journal Volumes for Sale

CANADIAN, TEXAS, Oct 15, 1896

To the Editor —Can you refer me to any one who can use eleven volumes of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Vols I to XI complete, bound and in good condition? Yours truly, CLAUDE WOLCOTT

PUBLIC HEALTH

Policemen Trained in Care of the Sick and Wounded —A letter to the *British Medical Journal* states that a trained "Samaritan" is always present at each police station in Berlin, and 1,500 men have been trained in ambulance work There are also "Samaritans" in each fire brigade The latter have cared for 1,533 cases since 1893

Providence Sewerage System —Residents along the west shore of Narragansett Bay, in the vicinity of Field's Point, are greatly disturbed over the sewage from this city The outlet of the mains is at Field's Point, and the tide carries the sewage along the flats to the west of Stave Goat Island and causes a constant nuisance The residents of Washington Park are also among the complainants, and attorneys are being consulted to ascertain their legal rights in the matter The sewerage system has just been completed and cost $2,000,000 It was thought by the Providence officials to be perfect, but it was predicted some time ago that an outlet inside of Warwick Neck would be useless It will cost several more millions to continue the system to a safe point down the bay

The Decadent American Birth Rate —France, to day, with all her industry, natural resources and ardent national life, finds herself face to face with this specter, and her statesmen are planning, by the modification of the inheritance tax law, to inspire a desire on the part of parents for more children In brief, by exemptions to families containing more than three children and by additional taxes on those with less, they hope to counteract the alarmingly crescent tendency of French married couples to rest content with very few "olive branches" In 1894 the birth rate in France was 22 to every 1,000 inhabitants, a decrease of 2 7 in a decade This is believed to be the lowest birth rate in the world, and no wonder thoughtful Frenchmen are aghast, and to this must be added the facts that illegitimate births and divorces are on the increase Our condition is by no means so bad, but it is bad enough to demand prompt attention and remedial efforts, if Dr Billings' latest figures be trustworthy In 1880 he says, our birth rate was 30 95 to every 1,000 people and in 1890 had dropped to 26 68 If it has pursued to now the descending ratio, it must be as we write, about 24 50, not 3 per 1,000 higher than the rate which frightens France It appears further from the eminent sociologist's researches that the class of parents best equipped to bring forth and educate children are the least inclined to this patriotic responsibility Into the causes of this we need not now enter and must content ourselves with simply entering a caveat —*The New York Press*

Regular Meeting Michigan State Board of Health, Lansing, Oct 9, 1896 —The meeting was called to order by the president, Hon Frank Wells of Lansing The members present were Prof Delos Fall of Albion, Mason W Gray, M D , of Pontiac, Judge Aaron V McAlvay of Manistee and Secretary Henry B Baker

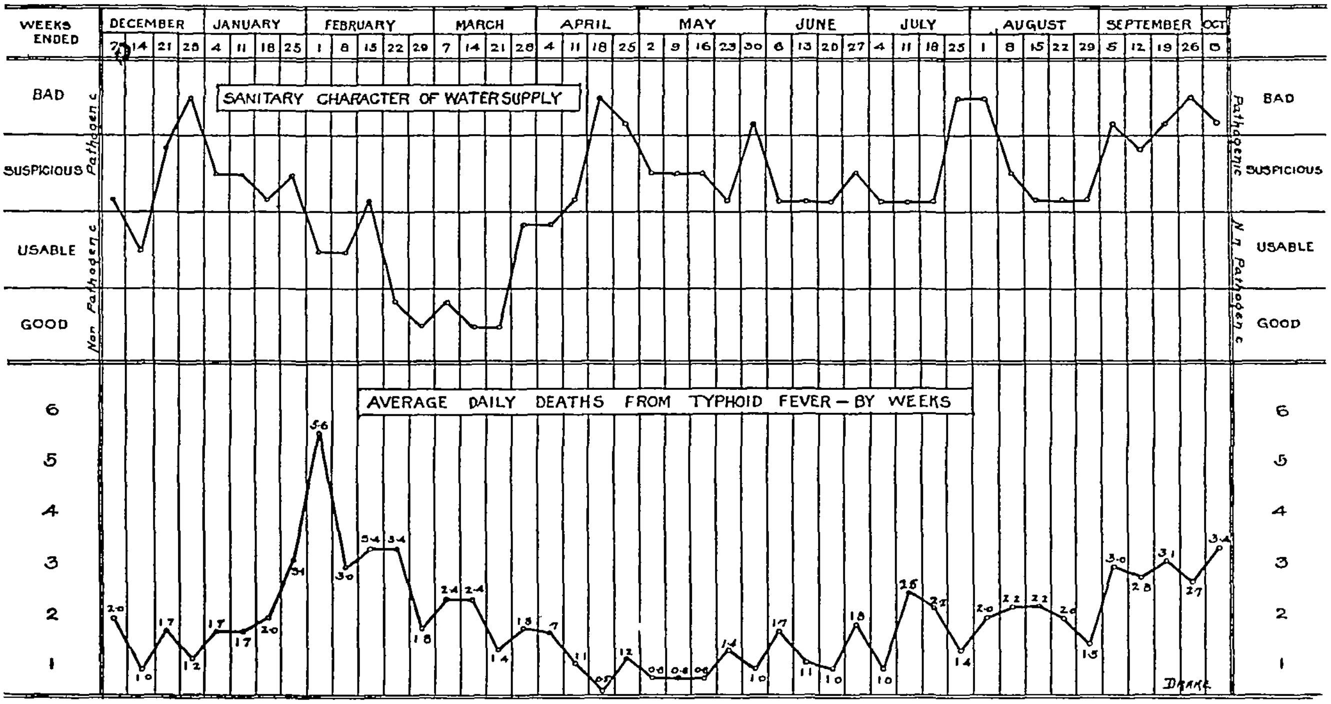
The regular business of auditing of bills and accounts was transacted The secretary presented his report of the conditions of health in Michigan and of work in the office during the quarter ending Sept 30, 1896 His report showed that the work of the office was fast being brought up nearer to date, and that work in connection with preparing the annual report of the secretary was progressing rapidly He thought that by Dec 31, 1896, his report for the year 1896 would be nearly completed The subject of the quarter centennial of the State Board of Health was suggested, and the board appointed the secretary a committee to report at the next regular meeting a plan for an appropriate celebration of the twenty-fifth anniversary of the establishment of the board, which should occur July 30, 1898

Doctor Baker said that during the past quarter he has occupied his spare time in ascertaining the results of the health work which has been done in Michigan, more especially for the restriction of dangerous communicable diseases The statistics collected by the Secretary of State and those collected by the State Board of Health agree in indicating that lives have been saved and sickness prevented which has resulted in saving to the people of Michigan over $1,000,000 per year The outlay has been very small The public health work of the State has, therefore, been exceedingly profitable In recent years the work has been greatly hampered for lack of money to properly distribute about the State the information necessary for the people to have in order to make the restriction of diseases as effective as it would be if all the people could be taught to cooperate in the work, nevertheless the results are very gratifying

Clinic Instruction in Infectious Diseases at London —According to the London *Lancet* for September 5, the facilities for clinic study at the public infectious disease hospitals has been materially improved during the past few years It says that while the importance of such study in the regular curriculum of undergraduates has long been recognized, but it is only within recent years that proper facilities have been afforded for taking advantage of the valuable material to be found in the fever hospitals of the Metropolitan Asylum Board "In former years the student had but few opportunities of becoming familiar with this branch of medicine, and it was by no means an unheard of event for a student to complete his career without having seen half a dozen cases of infectious disease That there is still evidence of the state of affairs which formerly obtained may be gathered from the fact that during 1895 no fewer than 1,277 patients, or a percentage on the total admission into the Metropolitan Fever Hospitals of 7 6, were after admission found not to be suffering from the diseases mentioned in the medical certificates upon which they were removed to hospitals, the percentage of mistakes at the Eastern Hospital at Homerton being 11 of the total admissions At the present time five of the admirable hospitals of the Asylums Board, viz, the Eastern at Homerton, the Western at Fulham, the Southeastern at Deptford, the Southwestern at Stockwell and the Northwestern at Hampstead, are open under certain conditions to students and medical practitioners, while instruction in smallpox is also afforded at the smallpox ships in the Long Reach near Dartford A student desirous of taking a course at one of the board's hospitals, must have completed his third year and have held the office of clinic clerk and dresser, he must then obtain the sanction of the medical school to which he belongs and pay a fee of three guineas for the first three months, and one guinea for each subsequent month to the clerk of the board, from whom he receives a card indicating the hospital to which he has to be attached At this hospital he must attend at stated times for at least two days in the week for a minimum period of two months, and on the completion of his attendance he receives a certificate from the medical superintendent whose lectures and classes he has attended While in the hospital the student places himself under the control of the medical superintendent and is bound to obey the regulations in force for the prevention of spread of infection These rules comprise the wearing while within the hospital wards of brown holland overalls, consisting of coat, trousers and cap, which are provided by the board, and the use of what may be termed a discharge block, which consists of an infected room where the overalls are left, a lavatory and a theoretically uninfected room The students are further required to keep their hair short and to be efficiently protected against smallpox A duly qualified medical practitioner has equally to conform to these regulations and obtain the consent of the medical superintendent of the hospital at which he elects to attend The student who attends these courses will obtain a fair knowledge of infectious disease, which will stand him in good stead in years to come, while he will also get an insight into the management of fever hospitals and the methods of disinfection practiced therein The provisions in regard to instruction in smallpox differ somewhat from the above, as it is necessary for the student to reside for from two to four weeks on the smallpox ships, where he is provided with rations, apartments and washing at the extremely moderate sum of 12 shillings per week The student has to travel to and from the hospital ships on the ambulance steamer and to furnish himself with a suit to which he does not attach much value, in order that it may be disinfected or destroyed at the termination of the period If the student can take this course during the summer we can promise him, as the result of a personal experience, a most enjoyable and instructive little holiday "

Typhoid Fever in Chicago —The diagram on the opposite page furnishes a most striking illustration of the relation of typhoid fever incidence to the character of a water supply—an illustration which, as the London *Lancet* has said of the first section of this diagram, reflects with mathematical accuracy the increase and decrease of the degree of pollution in the rise and fall of the death line Referring to this diagram in his "notes and comments" on the September report, the Assistant Health Commissioner, Dr Frank W Reilly, says that up to the close of September the daily analyses of the public water supply made by the city bacteriologist, Dr Gehrmann, and the city chemist, Mr Kennicott, show the water to have been "bad" 22 5 per cent, "supicious" 55 per cent, "usable" 10 per cent and "good" 12 5 per cent of the time since the first of the year During this period the death rate from the acute intestinal diseases and from typhoid fever—diseases directly related to impure water—has been higher than that of any other large city in the country and nearly double that of New York City The deaths from typhoid fever began to show a marked increase in August, 1895 During the twelve preceding months there had been a total of 455 typhoid deaths, or an average of 38 per month In August, 1895, there were 59 deaths, in September, 76, in October, 90, and during the twelve months ended Sept 30, 1896, there have been 751, an increase over the preceding twelve months of 65 per cent Comparing the first nine months of 1895 with the nine months of this year, the figures are January 1 to Sept 30, 1895, total typhoid deaths, 326, January 1 to Sept 30, 1896, total typhoid deaths, 559, increase in 1896 over 1895, *71 per cent* This is very nearly the death rate per 10,000 of population of the year 1889, immediately preceding the great typhoid epidemic of 1890 92 That year, 1889, the typhoid death rate per 10,000 of population was 4 83 The foregoing figures give a typhoid death rate of 4 63 for the past twelve months As compared with deaths from all causes the comparison is even more threatening The past twelve months have been much more healthful than 1889 in every respect except typhoid fever The total deaths (for the twelve months) amount to 23,676 or 14 62 per thousand of population In 1889 the death rate from all causes was 17 56 per thousand The present proportion of deaths from typhoid is 3 17 per cent of the total from all causes In 1889 it was only 2 67 per cent As set forth in the August report the unwholesome quality of the water has almost entirely offset the improved quality of the milk supply during the period, as shown by the deaths among infants and young children While there has been a marked reduction in the deaths of infants

DIAGRAM SHOWING RELATION BETWEEN
SANITARY CHARACTER OF WATER SUPPLY AND DEATHS FROM TYPHOID FEVER IN CHICAGO
DECEMBER 1895 TO OCTOBER 1896



under 1 year of age, who drink little or no raw hydrant water, the reduction of deaths among children over 1 year of age who do drink hydrant water has been less than 1 per cent

For a better understanding of the diagram it should be stated that the quality of the water is determined weekly from the combined chemic and bacteriologic findings for each day during the week Four qualities are designated "Good," "usable," "suspicious" and "bad ," and three degrees of each When the supply is designated as "good" or ' usable" the samples have shown an entire absence of any quality capable of producing disease When designated as "suspicious" or 'bad" the samples have shown qualities, at one or more times during the week, capable of producing disease The quality of "good" is determined by an entire absence of nitrates and nitrites, by traces only of free ammonia, by 001 100,000 or less of albuminoid ammonia, by entire absence of pathogenic bacteria, and by a count of bacteria of less than 500 per c c The quality of "usable" is determined by an entire absence of nitrates and nitrites, by free ammonia not in excess of 004 100,000 at any time, by albuminoid ammonia not in excess of 02 100,000 at any time, by an entire absence of pathogenic bacteria, and by a count of bacteria not more than 1000 to the c c The quality of "suspicious" is determined by any presence of nitrates or nitrites, by any excess of free and albuminoid ammonias beyond 004 and 02 respectively, and by any excess beyond 1000 bacteria to the c c whether it occurs on one or more days The quality of "bad" is determined by the presence of free or albuminoid ammonia beyond the above figures and of nitrates or nitrites, the presence of pathogenic bacteria and by a count of bacteria of more than 1000 to the c c The first, second and third degrees of the designated quality is determined by the more or less continual presence or absence of the factors of that quality and by the closeness to which the next quality is approached The presence of any one of the factors of quality, even when the others are absent, designates the quality and if they are all present, if only at one time, the highest grade of the quality is indicated In addition to this the average findings and their relation to one another—with respect to the proportion furnished by each tunnel to the total supply—are taken into consideration in the statement of the sanitary quality of the total supply The characterization is a matter of expert judgment and the figures in themselves do not always indicate the quality

The highest point, 5 4 of the typhoid death line, during the week ended February 1, is thus accounted for by Dr Reilly "For several weeks before that ended Dec 14, 1895, the water supply had averaged "usable" or "good," as indicated on the diagram, and the deaths from typhoid fever and from the acute intestinal diseases were below the average During the first 17 days of December the precipitation was considerably less than one half the average precipitation for this month during the previous 25 years—only 60 of an inch instead of 1 35 inches The sanitary character of the water supply improved from the first degree of "suspicious" during the week ended December 7, to the second degree of "usable" during the week ended December 14 On the 18th 1 10 inches of rain fell, on the 19th 2 66 inches, and on the 20th 1 67 inches, making a total of 5 43 inches in 72 hours or 3 09 inches more than the average total for the whole month This excessive rainfall flushed the sewage contents of the river and its branches into the lake and contamination was first noted on the 20th, increasing to the middle degree of "bad"—pathogenic—during the week ended December 28 The daily average of deaths from acute intestinal diseases during this week was 2 1 During the following week (ended January 4) this rate shot up to 8 4 per day—exactly quadrupled The typhoid mortality was affected more slowly—the incubation period being longer—but during the week ended January 18, this began to rise from a previous average of 1 65 deaths per day until it reached 5 4 per day during the week ended February 1 "

With the improved quality of the water, beginning during this week, the deaths began to diminish, so that between the weeks of February 22 and April 4, when the water was continuously "good" or "usable," the deaths declined from a daily average of 3 4 (Feb 15 22) to 0 5 per day in the week of April 18, and an average of less than 1 per day, for the eight weeks from April 11 to May 30 The pollution line culminated again in the week of April 18, since which time it has varied from first degree of "suspicious" to middle degree of "bad," and the death line has reflected this pollution at the usual interval —*at the end of the diagram averaging 3 4 per day*

Diphtheria and Typhoid Fever in Ohio —The following are the cities and towns in Ohio reporting an unusual prevalence of diphtheria and typhoid fever, since Aug 1, 1896 Diphtheria Minster, 39 cases, 6 deaths, Gervais 27 cases, deaths not known, Brilliant, number of cases not known, Byer, 33 cases, 19 deaths, Conesville, 12 cases, number of deaths not known, Five Point, 7 cases, 2 deaths, New Matamoras, number of cases not known, Bucyrus, 18 cases, 2 deaths, Franklin, 10 cases, 6 deaths, Ironton, 33 cases, 4 deaths, Portsmouth, 56 cases, 7 deaths, Cincinnati, 131 cases, 35 deaths, Cleveland, 170 cases, 47 deaths, Columbus, 17 cases, 2 deaths, Grover Hill, 15 cases, 1 death, Marysville, 29 cases, 2 deaths, Niles, 23 cases, Springfield, 59 cases, 14 deaths, East Liverpool, 28 cases, 6 deaths Troy, 11 cases, 1 death, Findlay, 14 cases, 5 deaths, total 23 places, 733 cases and 159 deaths Typhoid fever Gibsonburg, 105 cases, 9 deaths, Lancaster, 28 cases, Dyesville and neighborhood, 22 cases, 4 deaths, Conesville, 35 cases, number of deaths not known, Haydenville, 9 cases, Conneaut, 12 cases, 2 deaths, Cincinnati, 27 deaths, Cleveland, 40 deaths, Columbus, 11 deaths, Youngstown 104 cases, 11 deaths, Salem, 16 cases, 3 deaths, Mansfield, 34 cases, 3 deaths, Hayesville, 11 cases, 1 death, total 13 places, 374 cases and 111 deaths

Medical Practice Act of Illinois —Resolutions adopted by the Illinois State Board of Health, Oct 6, 1896

WHEREAS, the wise and progressive enforcement by our predecessors of the Act to Regulate the Practice of Medicine in the State of Illinois passed July 1, 1877, has resulted in a general, but not uniform improvement of the methods of medical education throughout the United States, and a material elevation of the standard of professional attainments and ability necessary to obtain the legal right to practice medicine in many States, thereby securing in such States a better equipped, more competent and more scientific body of medical men to the great gain and advantage of the people thereof, and

WHEREAS, this latter result has been attained to the fullest extent in those States where the college diploma is not recognized as final, but only as a qualification for examination by a board whose members are not connected with, or interested in any college or teaching institution, be it

Resolved, By the present members of the Illinois State Board of Health, with the fullest appreciation of the invaluable work of their predecessors, that Medical Education and the status of the Doctor in Medicine have outgrown the limitations of the Medical Practice Act of 1877, now, therefore be it

Resolved, That said Act should be so amended as to require, first, that all applicants for the right to practice medicine and surgery or any of their branches in the State of Illinois, shall demonstrate their fitness for such practice, through an examination by a board of impartial, competent and practical examiners, skilled in the various branches of medicine and surgery and no member of which board shall be connected or affiliated with or interested in any diploma granting college or teaching institution Second, that no applicant shall be eligible to such examination unless the legal possessor of a diploma of graduation from a medical college in good standing,

Resolved, That this Board earnestly invite the cooperation and assistance of kindred boards throughout the United States, to the end that uniformity of practice may ultimately obtain in the recognition of medical practitioners in all parts of the country, of all reputable medical colleges whose dignity and usefulness will thereby be promoted, of the medical profession of the State, as represented in the various medical societies, with the view of excluding the incompetent and unworthy from its ranks, and of the members of the forthcoming general assembly in this effort to protect the health and lives of citizens of the State —J W SCOTT, Secretary Illinois State Board of Health

SOCIETY NEWS

The National Sanitary Association —The second annual convention of this society was held in Brooklyn on October 14 and 15, Dr Frederic Jewett, president Important scientific business and the inspection of numerous public works important to sanitary officers in cities occupied the attention of the members to the full At the closing session, officers for the ensuing year were chosen as follows President, Dr F O Young, Lexington, Ky, vice presidents, Drs H C McLean, Brooklyn, N Y, F A Wilson, Meriden, Conn, and C S Benedict, New York, secretary, T E Veal, Esq, Atlanta, Ga, treasurer, J Hoadley, Esq, New Haven, Conn, executive committee, A R Moore, Esq, Brooklyn, N Y, Drs F A Jewett, Brooklyn, N Y, Wallace Sibley, Rochester, N Y, Archibald St George, Fall River, Mass, and J Hoadley, Esq The third annual meeting was named for October, 1897, at Lexington, Ky

The Sixty eighth Annual Congress of German Naturalists and Physicians —The Congress at Frankfurt opened with over 3,000 members inscribed, among them all the names most famous in science in Germany, Virchow, Leyden, Gebhardt, etc The Empress Frederic was also present as a member Some of the addresses are summarized elsewhere in the JOURNAL The proceedings were preceded by laying the corner stone of a monument to Sommering, a famous Frankfurt anatomist and physiologist, and, as the German papers state, the inventor of the electric telegraph

The Twelfth International Medical Congress —It is officially announced from Russia that no distinctions will be made against Jewish physicians coming to Russia to attend the Congress All that is necessary is to have their passports *visêd* at home by the Russian consul before they start, which is the regulation for all foreign members of the Congress Instructions to this effect have been forwarded to all the Russian consulates and embassies

The American Laryngological, Rhinological and Otological Society —The following circular has been issued

NEW ORLEANS, Oct 20, 1896

My Dear Doctor —The meeting of the Southern Section of the American Laryngological, Rhinological and Otological Society will be held in New Orleans, March 3 and 4, 1897 This date has been selected as it will permit visiting members to see New Orleans during the carnival season and will enable them to secure half rate railroad transportation We shall be pleased to have you attend the meeting and to receive from you the title of a paper, on a subject within the object of the Society, to be read before the meeting of the Southern Section The number of physicians who devote their attention to diseases of the ear, nose and throat has increased so much and the subjects for discussion have become so extensive that it is difficult in the time devoted to the annual meeting of the Society to give the necessary time to many important questions On this account, the four Sections of the Society have been formed, the object of which is to promote the interest of the specialty during the interval of the annual meetings A meeting of the Laryngological, Rhinological and Otological Society in the South is a distinctly new enterprise and should be encouraged With the active cooperation of the physicians interested in this work, the carnival meeting of the Southern Section of the American Laryngological, Rhinological and Otological Society will be an assured success

Candidates for membership should send their names, properly endorsed to Dr Robt C Myles, Secretary, 46 West 38th Street, New York, or to Dr W Scheppegrell, so that they may be acted upon by the Council of the Society Very truly yours,

W SCHEPPEGRELL Chairman Southern Section

MISCELLANY

Dr S C Stanton, formerly connected with the Chicago *Medical Recorder*, is now editor of the *Medical Standard* He is able and well qualified for the duty

Promotion —H W Sparks, formerly passenger agent for the Big Four Railroad, has been appointed traveling passenger agent, vice C W Norris, resigned Those who remember the kindess and courtesy extended by this gentleman to the passengers on THE JOURNAL special train to Atlanta, will be pleased to learn of his promotion

"Osteo malacia" Cured by Oophorectomy —The *Gaz degli Osp* of September 27, reports a case of severe and very painful osteo malacia cured by Piretti of Naples with a double normal ova iotomy, which it says should go on record as one of the really miraculous cures of modern surgery The improvement was apparent in a few hours, and it was soon complete and permanent, over a year having passed since then, with progressive restoration to perfect health

Death of Children from Hyperthermia —A recent discussion of this subject brought out several cases of apparently healthy children whose temperature rose suddenly from some inexplicable cause to 108 degrees F , most of them fatal Prompt cooling measures are the only means to save such cases Some ascribed the fatal result to heart failure Engel has observed a case of fatal hyperthermia following a warm "wrapping" in pseudo croup, which produced irregular action of the heart —*Deutsch Med Woch* , October 8

The South African Republic and the Geneva Convention —Information has reached this country on September 30 that His Excellency, Mr Bulaert Van Blockland, envoy extraordinary and minister plenipotentiary of the South African Republic at the Hague, forwarded to the Swiss Federal Council in the name of his government the act of adhesion of the South African Republic to the convention concluded at Geneva, Switzerland, Aug 22, 1864, for the amelioration of the condition of the wounded of armies in the field Prior to this the latest act of adhesion to the Red Cross Association was that of Siam in July, 1895

Rare Case of Gallstones —A recent number of the *Deutsch Med Woch* describes a bunch of sixteen gallstones evacuated in the feces without much effort and no previous disturbances except a violent brief attack of fever and pain in the abdominal region two years before The case was that of a woman of 46 years, who had worn a truss for umbilical hernia for sixteen years The bunch of unmistakable gallstones weighed 12 83 grams and measured three by four centimeters This recalls Morgagni's observation of a similar conglomerate which weighed 75 grams and consisted of sixty stones.

The Dumb Thermometer —The improvement in this thermometer consists in the absence of the scale, which is apt to depress patients who catch a glimpse of it, realizing the importance of the temperature recorded A small case fits over the instrument and a scale on this enables the physician to read the thermometer as he slips it inside after leaving the bed Mendelssohn thinks it may be found useful Dr R D Murray several years ago recommended the physician, in cases of yellow fever, to always use the centigrade thermometer, as the general public in America were unfamiliar with it, and therefore could view a high temperature without fear

The Indian Sacrifice —Under British rule the Suttee, the Juggernaut and other ancient sacrifices of human life have been done away with among the natives of India There is another huge sacrifice that remains to be attacked namely, the enormous waste of the lives of Indian women and children that is constantly going on from want of medical aid The customs of the country forbid the women from consulting men upon matters concerning the health either of themselves or their offspring The same reluctance, however, does not prevent them going to their priests, who administer most disgusting and abominable methods of treatment This should be a good field for medical women —*Med Press*, September 30

Special Hernias in Women —Waldeyer (*Centalbl f Gynäk* , No 30, 1896) demonstrated at a meeting of the Berlin Obstetrical Society some important anatomic researches as to the position of the ovary and other pelvic viscera He maintains that the ovary lies in a shallow pit, which is really a triangle of peritoneum elevated at its margins, *formed by the round* ligament, the umbilical artery and the ureter This pit is sometimes very shallow, but it may be very deep, so that the ovary lies in it practically in a state of prolapse, and the peritoneum may even form a hernial pouch, which has been found projecting into the lesser sciatic foramen or into the greater, either above or below the border of the pyriformis Waldeyer exhibited an incipient hernial pouch of this kind He likewise showed an inguinal hernia containing the Fallopian tube, and a pelvis with a defect in the symphysis pubis, into which a diverticulum of the bladder had forced itself

Mixed Clinical Classes —The announcement that Mr Jonathan Hutchinson has been compelled to exclude ladies from his popular clinical afternoons on account of the unwillingness of the male patients to undress before them is full of significance It is greatly to be regretted that this course should have been deemed necessary, for it places yet another obstacle in the way of the acquisition of clinical knowledge by women Doubtless, in the near future, the public will become as accustomed to women as clinical observers as to women cyclists, and will abandon foolish protests against the one as they have ceased to objurgate the other —*Med Press*, September 30

Bequests to Medical Charities —The contest over the will of the late Thomas T Wyman of Boston, by which $100,000, beside the residue of his estate, which is said to amount to $472,319, is left to various public charities, has been settled out of court The will was contested by certain relatives, and it is stated that the amount given to effect the compromise will only slightly diminish the residue of the estate The following medical charities receive $20,000 each The Emergency Hospital, the Cambridge Hospital, the New England Hospital for Women and Children, the Boston Lying in Hospital, the West End Nursery and Infant's Hospital, the Children's Hospital, the Massachusetts Charitable Eye and Ear Infirmary, the Sharon Sanitarium, the Boston Home for Incurables, the Consumptives' Home, the Carney Hospital and the Perkins Institution and Massachusetts School for the Blind The residuary legatees are the Massachusetts General Hospital, the Boston City Hospital and the Massachusetts Homeopathic Hospital

The Agglutinating Substance in Typhoid Serum —It is announced as the results of the study of the peculiar agglutinating properties possessed by typhoid serum (which is now a fully established fact) that the albuminoid substances, fibrinogen, globulin or casein, isolated from the fluids of a typhoid fever patient by certain processes (described in the *Bulletin de l'Académie de Médecine*, September 29) take away with them the agglutinating property and retain it at least to a certain degree They lose it in solution and recover it in their precipitate This fact is interesting not only to the physician but to the chemist, who may find in this agglutinating property some new reaction for the difficult study of albuminoid substances Others have discovered the same property in the serum in "proteus" infections

Normal Physiologic Standards in Mexico —It has been found that the atlases and charts published abroad and accepted as the standard of the normal individual do not apply to Mexico Vergara de Lope announces that in his investigations the characteristics of the urine, for instance, differ from those in other countries , it is more concentrated, less in quantity and lighter colored He ascribes the two former to the effect of the altitude on the intra vascular arterial tension, as the tension of the blood diminishes with increased rarefaction of the atmosphere He does not attempt to explain the lighter color, merely remarking that the hematic pigment, which some consider the cause of the coloration of the urine is present in this concentrated urine to excess and, therefore, the cause of the lack of coloration must be sought elsewhere —*Revista Quincenal*, September 1

When Licensing of Milkmen not Authorized —Where it is doubtful, after giving full force to all the provisions of a city's charter, whether the charter authorizes the licen- [illegible] lkmen the supreme court of errors of Connecticut holds, in the case of State v Smith, decided May 14, 1896, that it does not authorize it To illustrate The charter of the city of Bridgeport authorized the common council to make ordinances, not inconsistent with law, relative to commerce, to the inspection of produce brought into the city for sale and the election of inspectors for that purpose, to the sale or offering for sale of unwholesome produce of all kinds, to "licensing cartmen, truckmen, hackmen, butchers, bakers, petty grocers, or hucksters and common victualers, under such restrictions and limitations as said common council may deem necessary and proper" to the health of the city, and to "any and all other subjects that shall be deemed necessary or proper for the protection and preservation of the health, property and lives of the citizens" Here the court does not find authority for an ordinance excluding every one who has not received a license from the local health officer from participating in the business of a milkman within the city when the public statutes leave it open to all on equal terms

Convicted of Being an Unregistered Druggist —The defendant in the case of Queen v Simpson, according to a report in the Canada *Law Journal*, being owner of a large departmental store, was charged with keeping open shop for retailing, dispensing and compounding poisons contrary to the law of the Province of Ontario It appeared that part of his store was set apart for the drug department and was under the management and control of one Lusk, a duly qualified and certified chemist, registered under the pharmacy act, who dispensed the drugs, giving bills for the same on which defendant's name was printed, and on some of which his own name was also printed with the word "druggist" under it The defendant was never inside of the drug department nor interfered with the conduct of the business Lusk purchased all the drugs on his own judgment, but with the defendant's money, who received the proceeds, Lusk receiving a certain portion for his remuneration under agreement with the defendant Under these circumstances, the high court of justice of the Province of Ontario held June 16, 1896, that the matter must be remitted to the magistrate (who had dismissed the information) with instructions to convict the defendant

Formation of Urobilin —The conclusions of an article on this subject in the *Brit Med Journal*, October 3 are as follows 1 The bile pigment present in the upper part of the small intestine during its passage along the alimentary canal is converted into some colorless chromogen, to be again converted in the lower part of the small intestine into bile pigment 2 Urobilin is, as a rule, formed in the large intestine below the ileo cecal valve, and only rarely in the small intestine, that is to say, only in those parts where the intestinal putrefaction is most active 3 The staining of the wall of the cecum and large intestine with urobilin is due to postmortem diffusion, and is not any indication of the absorption of urobilin in the living animal Why it should in some cases be most marked in the cecum and just below the cecum, and not in the rectum, can only be explained by the fact that those parts are generally found in the postmortem room more decomposed than the rectum 4 The increase of urobilin in the urine, as well as having pathologic significance—as has been already recognized in cases of internal hemorrhages, such as cerebral, peritoneal or hemorrhagic infarctions and extrauterine pregnancy, and probably when red blood corpuscles are being destroyed, as in infectious fevers, scurvy and pernicious anemia—points also in favor of increased intestinal putrefaction, and may be a useful chemic test for such purpose

Photograph Evidence —In an action to recover damages from a city for injuries sustained through a fall alleged to have been occasioned by an inequality that had been negligently allowed to exist in a sidewalk, where the defense of contributory negligence was pleaded, it was contended by counsel for plaintiff that photographs of the place where the accident occurred should not have been admitted in evidence He argued that they did not tell the story told by the human eye, or in other words, that the picture they made to the apprehension was not the picture (of the obstruction in this case) made to the mind by the eye One of the illustrations used to show how little analogy there is between a photographic plate and the retina of the human eye, and that the imaging capacity and the character of the imaging performance of the former afford no just criteria of the imaging capacity and performance of the latter, was that the skin of the human face, which under the microscopic inspection of a physician is smooth and absolutely free from eruption, under the pitiless revelation of a photographic plate may be found to be dense with the pustules of smallpox But the United States circuit court of appeals does not feel that it can concur fully in this view of the question, holding, instead, that the trial court did not err in overruling the objection, and in considering the objection as going to the effect of the testimony, and not to its admissibility Scott v City of New Orleans, decided June 9, 1896 At the same time, it acknowledges there is much force in the suggestions of the counsel, and says that touching the effect of this testimony the jury should be fully and carefully instructed, and warned against its liability to mislead

"Douglasitis"—This is the name given by Condamin to the chronic inflammation of the recto uterine cul de sac, which differs from Schultze's posterior parametritis, as there is none of the tendency of the latter to cause retraction and afterward extension of the sacro uterine ligaments, and thus favor retroversion of the uterus Douglasitis is usually consecutive to salpingian lesions, but it also occurs as a primary affection, as Condamin has found in the course of four laparotomies Repose in the dorsal decubitus alleviates the pain of douglasitis much more readily than of salpingitis, and this is one means of diagnosis It is characterized by the multiplicity of the lesions, which can be palpated through the vagina by inserting the middle and index fingers, when not only the sacro uterine ligaments can be distinguished, but a number of small attachments, traversing in every direction the floor of the recto-vaginal pouch It is treated with massage, and systematic distension of the vaginal cul de sac by means of tampons (columnization), but if it does not yield to simple methods, and if there are diseased appendages, laparotomy is indicated, and after detaching all the adherences, etc , an anterior abdominal hysteropexy, to prevent the uterus from becoming displaced —*Lyon Méd* , September 27

Absorption of Medicines by the Vagina —In 1886, at the annual meeting of the Mississippi Valley Medical Association, Dr I N Love read a paper with the title "Artificial Alimentation and Medication," wherein he gave clinical evidence in favor of the vagina being made available (where the conditions would permit) as a medium for the administration of medicines and predigested food Ten years' additional experience has strengthened him in his views, and they are confirmed by a recent article in the *Collegione Italiano di Litture sulla Med* , No 2 It states that in one hour after the insertion of a tampon saturated with a 20 per cent solution of potassium iodid the urine contained iodin, the maximum of elimination being twenty four hours after application, and in forty eight hours no trace of iodin is found In the fever patients the absorption was very rapid, while in the hysterectomies it was not altered Iodoform is absorbed in small quantities, commencing seven hours after application and lasting twenty four hours To secure rapid absorption the vagina should be insufflated with fresh iodoform, which should be allowed to remain several days Salicylic acid is rapidly absorbed in large quantities, appearing in the urine in one hour and disappearing in twenty-four hours Salol is also rapidly absorbed, and remains for a long time traceable in the urine Antipyrin is also rapidly absorbed, appearing in the urine one and a half hours later, and remains for forty eight hours but the antipyretic power is less than when administered by the mouth The conclusions reached here are, in general, that the vagina undoubtedly has absorptive powers, and that these powers are increased in pregnancy and in the puerperal state and in the fevers —*Medical Mirror*, September

Improvements in Antitoxin —Behring stated at the recent Congress of Naturalists and Physicians, that the inconveniences which sometimes follow the use of antitoxin are due to the serum it contains, rather than to the antitoxins, as they are produced as frequently by injections of the serum alone Consequently he is striving to manufacture antitoxin in as concentrated form and with as little serum as possible It will soon, therefore, be more accurate to designate it antitoxic therapeutics, instead of serum Knoll's investigations have established the fact that the blood assimilates the entire amount of antitoxin injected, and that it is not taken up by the corpuscles, but by the fluid elements of the blood The antitoxins thus assimilated gradually vanish out of the blood again, until in eight days they are reduced to a tenth, and by the end of the third week they have almost entirely disappeared Behring asserts, therefore, that they positively confer immunity for at least three weeks, and not longer than eight or ten It is a curious fact that the length of the period of immunity is fixed, and does not vary with the quantity of antitoxin injected The conclusions of a recent critical and experimental study of the effects of antitoxin on the organism, by Poix in the *Presse Méd* of October 3, confirm Behring's statement that the accidents following the use of antitoxin are due to the serum and not to the antitoxins Poix warns against its use on tuberculous patients, as serious congestions, etc , are liable to follow in these cases Behring's resignation of his professorship at Marburg was not accepted, but he was given an extended leave of absence Beside the Hochst factory where the antitoxin is produced for sale, he has his private institution at Marburg, devoted to strictly scientific research, and the "standardizing" institute in charge of Professor Ehrlich, which is under government control —*Therap Woch* , October 4

Louisville

Annual Mortality Report —The report of Health Officer White for the past year contains much that is of interest He reports a total of 3,295 deaths, the death rate per 1,000 based on a population of 211,100 being only 15 5, death rate of whites, 14, and of colored 22 7 The report shows for the first time the prevalence of the contagious diseases as it is the first year that the reporting and placarding of these cases has been observed There were 137 cases of diphtheria with 72 deaths, a mortality of 52 5 per cent There were 238 cases of scarlet fever placarded, with four deaths There were 2,283 vaccinations reported, 724 diseased cattle were killed and 4,514 diseased cattle condemned and sent out of the city There were 225 stillbirths Consumption caused 370 deaths, typhoid fever 131 deaths, pneumonia 269, whooping cough 11 Of the total number of deaths 565 were under 1 year of age and 898 under 5 years of age Two thousand, four hundred and forty three were white, 852 colored 67 more male than female

Cincinnati

The Cincinnati Hospital has again broken into the editorial colums of the daily press and the present management is severely criticised for the manner in which the institution is being run During the past few days several women have escaped from the hospital and the last two give as an alleged reason for their action that they were almost starved The much promised reforms have so far failed to materialize The Board of Trustees have passed a resolution to ask the next legislature to appropriate $50,000 to make necessary improvements, the Board also refused the request of the Board of the Eclectic Medical Institute to allow their students to witness the operation (free of charge) on patients sent by the college

At the first meeting of the Academy of Medicine, Dr J C Oliver read a paper on the "Surgical Treatment of Epilepsy " He considered the operative treatment warranted in only a very small percentage of cases This week Dr R C Hill read a paper on "Intestinal Polypus as a Cause of Death "

The mortality report for the week shows Zymotic diseases 11, constitutional diseases 19 local diseases 36, developmental 10, violence 3 under 5 years 22 from all causes 79 annual rate per 1,000, 11 73, preceding week, 93 corresponding week 1895, 99, 1894, 87, 1893, 93

Dr Albert Snell has been arrested on a warrant sworn out by Dr Frank Winders, secretary of the State Board of Medical Examiners, charging him with violation of the medical practice laws This is the first arrest under the new law

The State Board of Health of Indiana have ordered all health officers of the State to provide themselves with a long glossy linen duster and skull cap to be carried in a separate bag and to be worn whenever they enter a building when any contagious disease exists

A case of hydrophobia recently developed in Columbus, Ohio The patient was bitten by a dog last July while attempting to give the animal, which had been bitten by another dog, some medicine For several hours before the man died it became necessary to strap him to his bed

Suit for false Committment —A woman residing in Columbus has recently entered suit against Dr W F Scatterday for $5,000, alleging damages to this amount as a result of her commitment in an insane asylum by the doctor, who was her physician She claims she was sane at the time

Washington

Health of the District—The report of the health officer for the week ended October 17 is as follows The death rate during the past week stood at 21 48, as compared with the average rate of 23 53 and with 26 80 in the same period last year The deaths reported to the health department numbered 116, of which 60 were white and 56 colored As compared with the late preceding weeks there was a slight decrease in the chronic brain, heart and kidney disorders, and in diarrheal complaints In those of the lungs and of children under 5 years old there was an increase Of diphtheria five deaths occurred, and none of scarlet fever The general health of the city, as indicated by the causes of mortality presented the same average above the normal as has prevailed throughout the fall months, the death rate running from 2 to three below the annual average per 1,000 inhabitants The new cases of diphtheria were 12, houses released from quarantine 8 and those left placarded 31 Of scarlet fever one new case reported, 2 houses released from isolation, leaving 5 placarded

District Medical Society—Toner Memorial Meeting —At the regular meeting of the Medical Society held on October 21 all regular business and papers were suspended and the meeting made a memorial one in honor of the late Dr Joseph Meredith Toner The meeting was called to order by Dr S C Busey, the president, who began the exercises by a most interesting life sketch of Dr Toner and closed his remarks by paying high tribute to his memory Drs W W Godding, Charles H A Kleinschmidt and J D Morgan read interesting addresses in his praise The papers read at the meeting will be published and distributed among the profession upon application

Adverse Report on a Dental College —A special committee consisting of Drs W P Carr, J Ryan Devereux, Clifton Mayfield, B F Odell and Henry Noble, appointed by the commissioners to examine the standing of the proposed Washington College of Dental Surgery, which has applied for a license to do business in the District, has submitted an adverse report All the committee except Dr Odell signed the report, which says "The college is just such an institution as the law proposes to keep out of existence It has no endowment or building, and its total plant is valued by the incorporators at $1,000 The faculty have not demonstrated any ability to teach, except in the National Homeopathic College, which was ruled out of existence by Judge Miller Two members of this proposed faculty were members of its faculty Members of the faculty of the proposed college admit that it is based upon the Washington Homeopathic Medical College dental department, whose plant they purchased and a majority of whose faculty they have absorbed, but proclaim their intention of raising the institution out of the metaphorical mud into which they admit it has fallen Their course and actions, however, when connected with the Washington Homeopathic Medical College dental department, and their present attempt to justify that course render it, in the opinion of your committee, extremely improbable that they will make any serious effort to do so, while their lack of endowment, lack of sufficient appliances and lack of eminent reputation preclude such a possibility, even in the face of earnest effort None of the members of the proposed faculty belongs to any reputable medical or dental society or association, regular or homeopathic, except one, who is now under investigation by the Dental Society of the District of Columbia for unprofessional conduct We would, in conclusion, call attention to the fact that Dr Odell, who was appointed on this committee, is also a member of the proposed faculty, and that while he was present at our most important meeting, he declined on the ground that he could not pass upon his own character, to sign any report of this committee "

Philadelphia

The Mutual Aid Association of the Philadelphia County Medical Society will hold its annual meeting on November 9, at the residence of the president, Dr John C Da Costa The eighteenth annual report will then be presented by the treasurer, Dr Geo B Dunmire The total amount of money now at interest is $12,889 63, an increase of $1,103 63 since the last report The members of the Association number 122, of whom 7 are life members The Association has two annuitants, one widow and one orphan daughter under its care

The Medical Schools opened their doors on the first of this month with an increase in the number of matriculants over last year Provost Harrison of the University of Pennsylvania formally opened the several departments He referred particularly to the new Dental Hall and the dormitories among the evidences of progress since last year Dr W M L Coplin, the newly elected professor of pathology and bacteriology at Jefferson College made the introductory address At the Medico Chirurgical, Dr Isaac Ott opened the session with a lecture on Claude Bernard and recent advances in physiology Dr Elizabeth R Bundy delivered the address before the students at the Woman's Medical College, particularly impressing upon them the importance of hygienic living and the evils of over study, and spoke on the baneful results of a resort to bromids or to narcotic drugs or the caffein bearing preparations She incidentally paid a well deserved tribute to the bicycle as a means of outdoor exercise for women and as an incentive to more rational dress

The College of Physicians held its first fall meeting on the 3d inst, the president, Dr J M Da Costa, in the chair Dr William J Taylor and Dr Chas W Burr read a paper entitled 'Report of a Case of Tumor of the Medulla Oblongata " It was remarked that the symptoms during life were insufficient to establish the diagnosis and the lesions found at the autopsy did not entirely explain the paralysis The patient was a woman, 55 years of age, who after some loss of power in the left arm and leg, complained of headache and double vision, with a tendency to fall to the left when walking Examination of the eye ground proved negative The loss of power gradually became more marked until paralysis became complete on the left side She then had an attack of pneumonia and died in convulsions The urine contained neither albumin nor sugar On removing the skull cap, the brain appeared at first to be normal, but on closer examination a growth was discovered involving the medulla, especially on the right side, projecting between the lobes of the cerebellum The tumor was found to be a sarcoma It was strange that with so much pressure on both sides of the medulla, that symptoms should have been produced only on the left side of the body The Sections of the College have all opened their winter sessions with interesting meetings and active discussions Dr B C Heist read a paper before the Section on Gynecology, October 15, on "Technique in Cæsarian Section," Dr Sprengle read a communication on "Prolonged Pregnancy," and Dr Chas B Penrose one on "Hysterectomy by Combined Operation through the Abdomen and Vagina " Before the Surgical Section, Dr Randolph Faries described a "Modified Form of Antero posterior Brace for the treatment of Pott's Disease " A death during the administration of ether was reported by Dr Jos M Spellissy Dr John B Roberts demonstrated a "Successful Operation for Cleft of Hard and Soft Palate," by the case of a patient Dr J William White and Dr Alfred C Wood reported on "Some Recent Cases of Renal Surgery "

The Philadelphia County Medical Society has been prospering under the presidency of Dr James C Wilson At the meeting on the 14th inst Dr F W Talley read a paper on the "Proper Position of Celio hysteropexy in Gynecology," Dr A O J Kelly reported four cases of "Essential Paroxysmal Tachycardia," and Dr Chas W Burr read a paper on "The Relation of Anemia to Chorea," in which any causative relation was denied, and the opinion expressed that when concurrence existed, it might be accidental or the anemia might be due to the chorea or to the causes which produced the neurosis

Mr William Macewen of Glasgow was recently entertained by a series of lunches and informal receptions, and received considerable attention during a recent visit to this city He expressed special interest when inspecting the new wards and recent improvements in the Pennsylvania Hospital, which is the oldest general hospital in this country

Detroit

The Michigan College of Medicine and Surgery opened with 100 students A building has been procured in addition to the college which will be used for extra clinics, general medicine and skin diseases There has also been lobby rooms fitted up for the students Dayton Parker has been elected to fill the chair of gynecology, vice E W Jenks, resigned, and W J Brand to lecture on anatomy

At the Annual Meeting of the Detroit Medical and Library Association held October 5, the following officers were elected President, H W Longyear, vice president, Frank H Walker, secretary, P C McEwen, treasurer, A P Biddle, librarian, Wm C Stevens After the election of officers, E T Tappey entertained the members of the society with a banquet

At the Regular Meeting of the Detroit Medical and Library Association held October 12, H O Walker presented some pathologic specimens, among the number being an ulcerated appendix with a fistulous opening The case was one of a history of several attacks, a suppurating kidney in which he had done a nephrectomy, also about twenty gallstones, for which the day before he had made the operation of cholecystotomy Each of the patients was doing well at the time of the report Theo A McGraw read a paper on ' The Utility of Omental Splints in Intestinal Surgery," in which he said that he felt warranted in bringing the procedure before the profession for discussion on account of its importance He also drew attenn to the fact that the omentum is extremely mobile, that it be drawn to any part of the intestinal tract that is covered h peritoneum. He said that in certain diseases it becomes ophied and in some persons is quite small, and especially s this so in tubercular subjects, where we find at the autopsy t a small remnant of the omentum. The Doctor said that at was characteristic of all peritoneal membranes was also of the omentum, the short period it takes to fasten itself to irritated surface and so acts as a bearer in preventing intra itoneal suppurations from becoming diffused, and that local d abscesses are frequently found in which the omentum has n the means of holding the walls intact, that a piece of entum applied over an intestinal fistula will after twenty r hours make a strong obstacle to the discharge of feces, d what is very desirable, this omental splint is very tolerant its surroundings, also that the practical value of the omen m splint is its application in wounds and fistula of the large estine, and that it made a safe union in operations on this cus. The essayist called attention to the fact that inflam- itions of the appendix are liable to result in suppuration uch invades the connective tissues behind the gut, that an scess also acted in the same way and might affect a large rtion of the intestine. When a bowel under such circum nces became torn or ulcerated through, its repair was excep nally difficult. He found that Lembert stitches in that gion were out of the question, as there is no peritoneum in ese desperate cases. There were only two successful proce res, one of which is the resection of the affected portion, and e other the closure of the fistula by an omental splint. He ported two cases which he had had at St. Mary's Hospital r C., aged 24 years, entered St. Mary's Hospital Jan. 1, 1895, th a suppurating appendicitis. The abscess was opened, and leaving the hospital after recovery, he was cautioned to turn at once for operation if there should be any recurrence November 26 he returned with renewed inflammation in at region, the appendix was removed and the adhesions oken. There was no rise of temperature or sepsis, but on e third day there appeared some thin feces on the edge of e wound, and it became necessary to remove the stitches he discharge of feces from the wound increased daily in quan ty, and soon there was an opening in the gut the size of one's tle finger. Practically no feces passed through the rectum d anus. Lembert stitches for this false anus were out of the estion on account of the absence, over a large area, of both uscular band and peritoneum. An incision was made in the ritoneum over the gut to the extent of 2½ inches, through hich cut the omentum was drawn out and fastened with tures all around the exposed part of the bowel, tucking well own behind and under the intestine. On the next day he had normal evacuation of feces. That which could not be accom lished by purgatives or enemata took place spontaneously, as on as the mechanical integrity of the bowel was restored. A an aged 39 years entered St. Mary's Hospital Dec. 11, 1895, th chronic appendicitis. On December 13, the appendix was emoved and the wound closed. A month later the wound eopened, fecal matter began to pass through it, and on his eturn to the hospital he was too weak for operation. About hree weeks later, his general condition having improved, the bdomen was again opened. The omentum was then brought own and wrapped in a large fold around the diseased bowel, nd fastened with sutures to the neighborhood of the wound, o that the wound was completely enveloped by it. Three eeks later he was sent home completely cured of his fecal istula. From these two cases it must be conceded that the alue of omental splints under these conditions is obvious yet r McGraw said that he should lay it down as a rule that, henever a lesion of a large intestine demanded a suture, the ne of union should, if possible, be supported by a thick layer f omentum, but that in wounds of the small intestine, this procedure was not necessary, although he would feel more safe from accident with this additional safeguard.

THE WAYNE COUNTY MEDICAL SOCIETY at its annual meeting October 1, elected the following officers: President, Geo. E. Frothingham; vice president, Lewis E. Maire; secretary, J. F. Patton; treasurer, C. Henri Leonard; board of directors, E. B. Smith, Frank S. Hough, T. J. Parker, O. P. Eaton and Kenneth Gunsolus. On the same evening the retiring president, E. B. Smith, read his annual address, after which the retiring secretary, Frank S. Hough, presented his report, which was approved. At the regular meeting of the Society October 8 (memorial night), E. B. Smith read a biographic paper, taking up the lives of Wm. Brodie, who had been president of the Wayne County Medical Society a number of years; Henry F. Lyster, S. D. Richards, C. J. Lundy and August Kaiser, all of whom had been prominent members of the above society.

Annual Report of the Surgeon General of the Navy.—Surgeon General Tryon, chief of the Bureau of Medicine and Surgery, has submitted his annual report to the Secretary of the Navy. Estimates have been submitted for two ambulances for use at the naval hospital at Portsmouth, N. H., and Mare Island, Cal., where they are urgently needed.

"The cemeteries of the several naval hospitals have had very little done for them since the war and in no way creditable to government establishments," says the Surgeon General.

"Special appropriations will be required for each one to place them in a condition that they can be cared for in the future by the hospital force.

"Attention is again called to the necessity of providing improved accommodations for the sick and wounded on board vessels of war, and to the assignment, when practicable, of sufficient space on the gun deck for hospital purposes."

The Surgeon General says that the passage of the bill organizing the army hospital corps has already proved of great benefit to the militia of the different States, and the passage of a similar bill for the navy would also be advantageous to the naval militia, now being rapidly organized.

AMBULANCE OR HOSPITAL SHIPS.

A strong argument is made for ambulance or hospital ships specially fitted up. Considerable attention is now being paid to the construction of such vessels abroad, and it is universally conceded that they should be designed and built for this particular duty, and considered an essential part of the fleet of war.

The health of the navy is reported as good. The care and comfort of the sick and wounded of the navy have been much improved by the adoption of iron swinging cots for sick bays of all vessels, and the establishment of an ambulance service at the naval hospitals at Chelsea, New York, Philadelphia and Norfolk.

FOOT BALL AT ANNAPOLIS.

In a short chapter about the Naval Academy, the Surgeon General says:

"The good health of the station has been maintained throughout the past year. There were nineteen admissions, involving sixty one sick days, for injuries received at the game of foot ball, and ninety excuses from drills from the same cause. The injuries consisted of one luxation, two fractures of bones, one inguinal hernia, two cases of concussion of the brain, and a number of minor sprains and contusions.

"Attention is called to the unsuitable character of the academy buildings, many of them being badly ventilated, unsatisfactorily lighted and heated, and some of them in a condition almost beyond repair.

"The sewerage system of the academy is defective and unsatisfactory, and proper means should be adopted for carrying the sewage into deep water at some distance from the academy grounds.

IDENTIFICATION OF RECRUITS.

In regard to the identification of recruits, the Surgeon General says:

"In consideration of the effect upon the discipline and general tone of the enlisted force of the navy, the importance of preventing deserters and dishonorably discharged men from re entering the service has caused the question of the identification of such undesirable persons to be carefully investigated.

"The anthropometric system of M. Bertillon presents the advantages over other methods of conformity to scientific requirements and capability of indefinite expansion.

"The system employed by the United States army is a modification of the above, in which personal marks or characteristics take the place of anatomic measurements, and since its adoption in 1889 has been attended with excellent results, as shown by the detection of a large number of deserters and the progressive diminution in the number of undesirable candidates presenting themselves for enlistment"

The bureau is at present considering some plan of combining, modifying and selecting from these two systems a method especially adapted to the requirements of the naval service

VACANCIES IN THE MEDICAL CORPS

The continued impossibility of filling vacancies in the medical corps is reverted to by Surgeon General Tryon in the following words

The record during the last fiscal year is nearly a repetition of the figures presented in the last annual report There were 341 applications made to the department for appointment as assistant surgeons in the navy Out of the number only thirty six applied for permission to appear before the naval medical examining boards

Of the 36, 22 availed themselves of the opportunity to appear before the boards, and of this number there were 4 rejected physically and 12 rejected professionally leaving only 6 out of the 341 original applicants, representing every section of the country, who were found qualified for appointment as assistant surgeon

This state of affairs has existed for years, and will undoubtedly continue until there is some favorable legislation for junior medical officers of the navy

At this date there are 10 vacancies in the grade of assistant surgeon, and the bureau is embarrassed by not having a sufficient number of medical officers to fill important stations ashore and afloat

Many ships and hospitals are kept without their legitimate quota of officers, and, unless this is in some way speedily remedied, by reason of increase of men in the navy and number of new ships placed in commission annually, serious consequences must follow On account of the great number of vacancies existing and the probability of the number increasing instead of diminishing, it is strongly urged that the recommendation contained in the bureau's letter addressed to the department on the subject, dated Feb 8, 1896, be approved, that "a special law be enacted authorizing the Secretary of the Navy, during the present exigency, to appoint acting assistant surgeons for temporary duty in the navy until the number of vacancies in the regular medical corps of the navy are filled" When this is accomplished, their services can be dispensed with and no further appointments made, except in time of war or until additional vacancies occur in the assistant surgeons' grade

In regard to local institutions, Surgeon General Tryon says

WASHINGTON NAVY YARD

The sanitary condition of the yard during the past year has not been satisfactory During the summer and autumn months malarial fever of a severe type prevailed extensively, a large proportion of the cases being of a remittent character During the year there were 250 admissions and 48 readmissions to the sick list Of this number 216 returned to duty and 79 were transferred to hospital

There was a loss of 1,021 days from sickness, due principally to the large number of cases of malarial fever

Reports have been received that apprentices transferred from this yard to other stations all suffered from attacks of malarial fever, undoubtedly due to climatic exposure while undergoing instruction at the yard

MARINE HEADQUARTERS

The health of the post has been satisfactory during the past year except that in the months of September, October and November an unusually large number of cases of malarial fever prevailed, which undoubtedly was caused by the insanitary condition existing at the navy yard, which was made the subject of a report by a sanitary board to the department in May, 1895

Beyond some minor improvements in the introduction of modern water closets and bath tubs, there has been no change in the general sanitary condition of the post

NAVAL HOSPITAL

No material changes have been made during the past year in the hospital grounds The paving of 10th street east which has been commenced, will add much to the comfort of the hospital patients The hospital is now being furnished with a modern operating room, properly equipped for the performance of operations, and it is hoped that it will be completed at an early date

The necessity for increased accommodations for the sick at this establishment is apparent

The records of the hospital for the five years 1891 to 1895, inclusive, show 36 admissions of officers, with a total of 1,265 sick days, other admissions, sailors and marines, number 528 Patients are supplied to this hospital chiefly by the navy yard and marine headquarters, but from time to time they are transferred here from other hospitals, from coast survey vessels and from other vessels, foreign or belonging to our own navy, which may be in port, also old sailors and marines on the retired list who have no suitable home and when taken ill find a refuge here

The officers attached to the navy yard and marine headquarters number about 50, while the number of sailors and marines is about 240 Beside the above, there are in and about Washington 250 or more officers, active and retired, liable to need hospital accommodations and treatment

The situation of the hospital is excellent, occupying an entire square of land on four streets, having thus abundant sunlight and fresh air The elevation above the navy yard is inconsiderable, but sufficient to make a very great change perceptible in the condition of malarial patients transferred The mere change from the one place to the other has sometimes sufficed to put a stop to an attack of malarial fever

There is but one separate room in which a sick officer can be isolated Additional accommodations should be provided, so that the whole of the two principal floors could be allotted to patients, the lower or main floor and the second floor to the enlisted men The medical officers on duty should be lodged in an annex, which could be easily built within the present grounds and in connection with the hospital proper, and an appropriation with this object in view should be submitted at an early date

---

THE PUBLIC SERVICES

Army Changes Official List of changes in the stations and duties of officers serving in the Medical Department, U S Army, from Oct 17 to Oct 23 1896

First Lieut Benjamin Brooke Asst Surgeon, leave of absence granted on surgeon's certificate of disability is extended one month on surgeon's certificate of disability

Major Clarence Ewen Surgeon, leave of absence granted on surgeon's certificate of disability is still further extended one month on account of disability

First Lieut Charles F Kieffer, Asst Surgeon (Ft Crook, Neb), is granted leave of absence for two months to take effect upon the completion of his duties with the Third Artillery

Navy Changes Changes in the Medical Corps of the U S Navy for the week ending Oct 24, 1896

Asst Surgeon M S Elliott, ordered to naval laboratory and department of instruction, New York

OPERATION FOR THE CURE OF HERNIA VIEWED FROM A MEDICO-LEGAL STANDPOINT

Read in the Section on Neurology and Medical Jurisprudence at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Georgia May 5 8 1896

BY HENRY O MARCY, M D
BOSTON MASS

The revision of the duties and obligations which the medical profession owe to their constituency must be made in every advancement of science From this standpoint it is pertinent to inquire, if the demonstration of the easy and safe cure of hernia is not sufficiently ample to demand from our profession a revision of opinion, which only a brief period since would have been accepted as unquestionable? Few will deny that every sufferer from hernia, even in its less pronounced forms, is not alone incapacitated in a considerable degree for the discharge of certain duties incumbent upon a great variety of occupations, but also that there is a recognized life risk, incident to the individual This has long been accepted in life insurance, examinations for the public service, etc It is also conceded that, at the best, instrumental supports are disagreeable make shifts, and that the usual history of the subject of hernia is an increased physical disability

From the medico-legal standpoint, may it not be considered as an open question, whether this entire class of sufferers have not rights which should be respected, when such life interests are entrusted to the watchful supervision of their medical and surgical advisers If this be true, does the surgeon discharge his full duty to the one seeking his advice, disabled in large degree from an irreducible or uncontrollable hernia, who offers *simply* the palliation of rest, condemning the patient to the wearisome watching for relief which only death can give? If such queries throw a new light upon the ever increasing burden of responsibility, which the advancement of science places upon him who would be its exponent, what becomes the plain duty of the physician, the rank and file of the profession, who are ever in close touch with this great army of invalids, and, as a consequence, must decide promptly the course to be taken in the constantly recurring cases of intestinal obstruction caused by strangulation?

I need not cite even recent experiences to show the still high death rate in all hospital practice, occurring from delayed operations for the relief of intestinal constriction, delays made fatal not by the gravity of the operation itself, but by the conditions which render operation necessary

The early operation for the relief of these conditions is attended by a very minimum of danger, which, however, increases in geometric ratio with every passing hour, and yet the average sufferer from acute intestinal obstruction from hernia, is liable to neglect at the hands of his medical adviser, and it is the object of this paper to emphasize this neglect as criminal before the law There is but one duty for the physician Immediately upon the recognition of the condition, relief must be afforded Taxis is no longer warrantable as advised at an earlier period, since this alone often inflicts irretrievable damage upon the constricted intestine An anesthetic should be at once administered and, if in the relaxed condition of the parts, gentle manipulation does not restore the displaced organ, the operation must be immediately performed

It is not necessary to give examples of almost daily flagrant violation of this simple, surgical axiom In my experience the series is long and includes many instances which have come under my observation as a consultant, where from a medico-legal standpoint, I unhesitatingly declare that the neglect of prompt surgical procedures was criminal

Appealing to the fear of the individual is one of the most reprehensible ways of quickening his conscience, especially in our profession, the members of which are supposed to be actuated in the discharge of their duties to suffering humanity only by motives of the highest and most praiseworthy character Courts of law are constantly dealing with questions of damage, arising from alleged incompetence, because of the improper restoration of fractures and dislocations, injuries from which a life risk may never be involved and on account of this surgeons are constantly thoughtful to guard against medico-legal complications, seeking consultation for self-protection much more than for the benefit to be derived by the patient If this was recognized as a possible sequel to every case of the severer forms of hernia under supervision, it would be of great advantage to the patient, to the physician, and the profession at large

The causes of hernia should be much more carefully studied and understood A thorough anatomic knowledge of the parts involved, their functions, and pathologic changes must be acquired Such knowledge is of the first importance in many medico-legal cases Indeed, the general opinion is that hernia is produced by some violent strain, or accident, for which in the general mind the term rupture is a synonym, that is, a sudden giving away of the parts involved A superficial study of the case might lead one often to arrive at this conclusion This is so exceptional that it represents a very minute fraction of the total

I was called as an expert in court where a town had been sued for large damages, the injury claimed to have been received by a man in middle [illegible] the consequence of a fall into a hole in [illegible] came ruptured The hernia was [illegible] inguinal type, and doubtless was the [illegible] series of antecedent causes, probably commencing in a congenital non-closure of the canal Yet the jury awarded the claim and damages, more from the general belief that such injuries must be the result of sudden violence, rather than from the testimony offered

On the other hand instances are not wanting where injuries have been inflicted upon large scrotal hernias, even resulting in death, and here may arise a nice point at law, to determine if the individual is liable to recover under such circumstances, when modern surgical opinion teaches that such a man is in daily possible risk to his life from a condition which is amenable to cure by surgical interference of moderate danger

In this phase of the subject there is also a very constant factor of a material type represented by a money equivalent This has its exponent in the large number of soldiers of the late war borne upon the pension rolls, disabled because of hernia Some time ago at a meeting of a large number of surgeons, it was desired that I should give a demonstration of my method of operating for the cure of hernia before the members in attendance A proper case was selected by a local surgeon, the man having been for years under his observation partially disabled on account of a large scrotal hernia The suffering was freely acknowledged, the desire for relief so great that preparations for the operation had been partially arranged It was finally refused, the sufferer admitting that the hernia was worth to him as a pensioner of the United States government $150 per year, and that he would rather endure the disability, than deprive himself of his assured income

I have no hesitancy in declaring that it is the duty of the government to afford this large class of sufferers free of expense, an opportunity to be cured of this troublesome and dangerous affliction, and in the event of their refusal to accept the same, order that the pensioner's name be stricken from the roll

The statements made in this brief paper may seem radical to many, indeed to a degree revolutionary, but I offer them in the full conviction that they are the expression of a just surgical conservatism, and I believe the time is not distant when they will be accepted and amplified

I look upon the verdict of this Section of the Association to which this contribution is offered as most important in establishing a new status of opinion upon a surgical subject which must be far reaching in results, involving not only large monetary interests but also pregnant with the salvation of many lives

DISCUSSION

Dr Hughes—I think the suggestions are practical, new and destined to prove of great value to mankind I think the surgical section ought to join in their recommendation, that the pensioners should be offered the opportunity to secure the advantage suggested in the paper I would not say that they should be *compelled* to do that or throw up their pensions I doubt if this can be done under the law The Constitution of the United States provides that no man can be mutilated in any way We used to have a law in the State of Missouri providing for the castration of men who committed rape It stood on the statute books until some astute lawyer carried it to the supreme court, and it was declared unconstitutional

Dr Moyer—I was glad to hear Dr Marcy refer to the relation of accidents to hernia More than ten cases have been sent to me for examination by attorneys, claiming that the rupture was caused by a fall or sudden injury In nine of those cases I gave the opinion that I did not believe that injury and accident caused hernia

Regarding the doubtful case, the rupture was not at the usual site, but was at the linea alba, midway between the umbilicus and the pubes

Dr Hughes—I would like to ask Dr Marcy whether he maintains in that paper that accidents are not frequent exciting causes

Dr Marcy—I do not

Dr Moyer—I think, however, that is the later and more general view of the matter

Dr Hughes—I have always been under the impression that it is a frequent cause Anyone who is intimately familiar with the personnel of soldiers, and has had large numbers of them to treat—I had an average of 10,000 men under my care during the war in what was called a "straggler's camp"—has doubtless had considerable experience with hernia Men were constantly coming to me to be examined whom I had in my own command, and whom I had examined personally as to whether they had abdominal or inguinal hernia, finding them apparently sound in that regard—these very men, would develop hernia from the time they were forced suddenly to jump out of cars, owing to a surprise or an attack I never supposed that the sudden jar was the cause of the hernia, but was the exciting condition

Dr Bishop, of Pennsylvania—If Dr Marcy's paper would convince people that the operation is comparatively a safe one, and that the danger by not having the operation is greater it would certainly be well Trusses are as dangerous as patent medicines

Constant tension—railroad men getting on and off trains, plasterers or painters working overhead, etc, has a tendency to precipitate this trouble I have advised the use of suspensory bandages in such cases

Dr Marcy—A careful anatomic study of the inguinal canal in the male exhibits one of the most beautiful of nature's provisions for protection and safety The cord traverses the abdominal wall in an oblique direction, so pronounced that the intra abdominal pressure causes a complete approximation of the walls of the canal, acting always, when in the normal condition, at or near a right angle to its axis The transversalis fascia is extraordinarily strengthened and thickened so as to produce a firm, inelastic support posteriorly, while the internal ring is reinforced about the cord in a way to prevent a peritoneal depression about its upper border The testicle finds its way out of the abdominal cavity at such a late period of the intra uterine life that the developmental processes, which result in the normal closure of the canal just referred to, are often imperfect When not complete there results a depression in the peritoneum above the cord, which affords a point of yielding to the intra abdominal pressure, although it may never result in hernia Often this condition remains unnoticed until in a later period of life, when the muscular tonicity of the abdominal wall is lessened, a yielding occurs, and by a slow process hernia develops This I believe to be the common cause of inguinal hernia in the male Any one who will take the trouble to examine postmortem will note that traction upon the cord in a very considerable percentage of adults demonstrates this condition more or less marked, although it has never advanced to a degree which allows the protrusion of any portion of the abdominal contents into or through the canal Cloquet, of Paris, in the earlier part of this century, made careful dissections of 500 cases of hernia subjects, recording minutely the conditions found He describes and figures a condition of normal anatomy under the name of the infundibular process of the peritoneum I can not doubt but that which he describes as normal is pathologic, and results from imperfect closure of the canal in the early months of existence

That muscular strain of itself in the normal individual is not the cause of hernia is evidenced by the extraordinary play of muscular activities in the gymnast, who in every conceivable way exercises an enormous strain upon the abdominal wall, yet so far as I have been enabled to learn the circus athletes and rough riders of the West are not more liable to hernia than are those of less active occupations

---

USE OF THE STOMACH AND RECTAL TUBE IN CHILDREN

Read in the Section on Diseases of Children at the Forty Seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5-8 1896

BY W JAY BELL, M D

Assistant to the Chair of Obstetrics and Clinical Gynecology, Southern Medical College ex Assistant Resident Physician of the New York Infant Asylum

ATLANTA, GA

I am fully aware that the stomach and rectal tube is not so generally used in the south as in the north and northeast Having followed their use so closely during my service on the staff of the New York Infant Asylum and since my location in Atlanta, and having such pronounced beneficial results following their use, I am constrained to present a short paper on the subject before this body

We may well deem our age the most practical in the world's history and we find theory quickly receding to give place to the tangible and practical

The approaching warm season causes one who handles the little ones to stop and reflect for a time upon the too often fatal ileo-colitis and gastro-enteritis There is nothing to be found infallible in medicine nor in means, yet we must accept all available means and apply them judiciously yet assiduously

Often one will be called in to a little patient with a history that the child takes food well, even hungrily, but in a short time suddenly vomits the sour contents of the stomach, this result following each feeding Now, all are familiar with ferments A fermentative state often accrues in the stomach causing fermentation of the stomach's contents with irritation and consequent vomiting, yet the vomiting does not entirely free the stomach of ferment, there being a nucleus of fungus remaining which infects the next food taken and persistent vomiting is the expected consequence Then what steps must we take to relieve this class of cases? The cause of persistent vomiting is retained ferment Then the most practical step will be to remove this factor of irritation It is in this class of cases that the most happy results are obtained from a thorough irrigation of the stomach

Imperfect digestion is frequently found in the little patient, this may be due to want of digestive power or fermentative interference with digestion An irrigation of the stomach two or two and one-half hours after feeding and giving a subsequent rest of at least one hour will be met with gratifying results Athreptic or poorly nourished conditions are found due to a failure of the child to take nourishment, in these cases gavage is often necessary and will often be followed with happy results In this the same tube may be used, being careful to cleanse

It was our custom in the New York Infant Asylum to use a tube, which consists of a funnel of glass or hard rubber, with a piece of tubing two or three feet long, to the end of this is attached a small stomach tube or large catheter having a small piece of glass tube intervening for observation This is a complete tube for either feeding or irrigation With tube, a pitcher of warm water and a slop jar or pan you are fully equipped With the patient in the lap of an attendant or mother, having the face to the physician, the tube is moistened and with the left index finger as guide pass the tube steadily into the stomach, with funnel raised above the patient's head fill the stomach to full capacity and, lowering the funnel, syphon off the stomach contents, repeating this until all return is clear After irrigation a rest of about one hour should be given the stomach before giving nourishment Flax seed water for a few feedings is best

Gavage is accomplished by passing the tube and pouring into the stomach the amount of nourishment desired, being careful to compress the tube and hold the mouth well open for a moment after the removal of the tube until irritation of throat passes off, which will prevent regurgitation The stomach tube is useful in many other forms of gastric irritation, but I will not go further It is, indeed, a most practical instrument to have on hand at all times and especially in cases of poisoning

The rectal tube is far more generally used than the stomach tube Dr Seibert of New York, says that the first thing that he does when called in to a case of convulsions in a child is to draw out his fountain bag, call for a pitcher of hot water and proceeds to irrigate the colon at once While the contents of the rectum and colon are not the sole cause of convulsions, yet such a vast majority of these cases are due to, or irritated by bowel contents that the step is a most wise one The apparatus which I use and which is used in the New York Infant Asylum, consists of a fountain bag with a small stomach tube attached, and no better apparatus could be devised except that a return attachment may be used The indications for the use of the rectal tube are so manifold that it would require too much time to do more than briefly refer to some of them It is fully established that the rectal and colon contents are often most potent factors in hyperpyrexia I have observed in a number of cases a marked fall of temperature from irrigation of the colon

In ileo colitis, gastro-enteritis, fermentative and catarrhal colitis, cholera infantum and other forms of fermentation and infected bowel contents, most gratifying results will often follow the use of the tube in high rectal and colon irrigation Now, it is important that not only the rectum but also the colon should be irrigated The tube should be passed as high up as the transverse colon which can be easily accomplished, with the child in dorsal position on slightly inclined board, table or bed, the tube is vaselined and passed with a slight rotary movement bearing in mind the course of the rectum through the curve of the sacrum and upward over promontory to the left, and the tube will pass readily into the colon and up with ease to the transverse colon when the stream is turned on and continued until bowels are thoroughly irrigated

Efforts to influence the fluid to pass up the colon by placing the child on left side and lowering the head and the trunk, is to me quite unsatisfactory and but slight cleansing effect can be obtained in this way, but with the tube well up into the colon, a far more satisfactory irrigation can be accomplished

In persistent dysentery I have obtai d good results from irrigation, after w [illegible] xseed water with a small amount o [illegible] In cases of gastro-enteritis I hav [illegible] s follow irrigation of both stomach and rectum and am convinced that this step would be wise in a beginning cholera infantum, using rectal irrigation quite hot for stimulating effect and to this may be added a small amount of salt and alcohol In habitual constipation the use of the rectal tube is preferable to a too frequent use of laxatives In this, however, a high irrigation is unnecessary Irrigation is a step that should always be taken in cases of convulsions in children

---

INFANTILE SCORBUTUS

Read in the Section on Diseases of Children, at the Forty seventh Annual Meeting of the American Medical Association held at Atlanta Ga May 5-8 1896

BY ALBERT H BURR, PH B , M D

CHICAGO

Dr William P Northrup, editor of the chapter on Scorbutus in the "American Text-book of the Diseases of Children" (1895), says "The reader will find in this book for the first time scurvy put down as a disease occurring in the United States" It is barely two years since he tabulated some twenty-six American cases, and directed attention to a disease of infancy hitherto overlooked in this country because of its rarity or because of failure in differentiating it from the somewhat kindred disease of rickets, since that time the interest awakened by the discussion of Northrup's papers has brought out reports of a number of cases from observers in different parts of the country From this it would seem that the disease is assuming greater importance by reason of its increasing frequency in these days of degenerate mammæ, supplemented by the growing indisposition of American mothers to suckle their young, on the one hand, and on the other by the commercial enterprise and ingenuity of man in devising sterilizers and proprietary foods to meet a long-felt want in the failing maternal fluid and motherly instincts Between these physical and mental degenerates and the chromo-advertised infant foods, represented as perfect(?) substitutes for mother's milk, the coming baby must run fearful odds in its unequal struggle for existence Authorities tell us that 25 out of every 100 babies die before the end of the first year, and of these 25 only 4 die at the breast while 21 perish at the bottle What sadder comment is to be found on modern civilization?

To W B Cheadle of London is due the credit of first recognizing infantile scorbutus on clinical grounds In 1878 he published three cases on account of spongy gums, and obscure symptoms referred to the lower limbs, which he maintained were cases of true scurvy Soon after this, Thomas Barlow commenced his postmortem investigations and immortalized his name by establishing a pathologic basis for the disorder, which German writers had described as acute rickets The results of these valuable and conclusive labors he published in 1883 and confirmed the views of Cheadle Barlow's classic review of the disease in his Bradshaw lecture of November, 1894, leaves but little to be added to our knowledge of this, now inexcusable and easily prevented, disease

Etiology —Briefly stated, he says "The prolonged use of a defective diet induces the symptoms"

Pathology —"The essential lesions are subperiosteal blood extravasation and its secondary sequences," hemorrhages into the center of the shafts of the bones, producing absorption of the trabeculæ and leaving them brittle and easily fractured effusions of blood into surrounding muscles and cutaneous tissues, with progressive anemia resulting from these multiple hemorrhages

Diagnosis —The diagnostic differentials between scorbutus and rickets are of chief interest and consist in the hemorrhagic phenomena and their sequelæ, the pseudo-paralysis, spongy gums where teeth are present and the rapid, almost magical improvement under antiscorbutic diet

The following case came under my care Dec 12, 1895

Dorothy R , thirteen and a half months old, had been brought to Chicago from a distant State by the advice of the family physician to be treated for a supposed spinal trouble She was placed under the care of one of our best orthopedists The diagnosis was rachitis, with slight spinal curvature As the child was too weak for any corrective appliances the specialist addressed himself to general tonics and restoratives with the view of improving the anemia and malnutrition At the end of six weeks the child, which at first seemed to be materially improved, was found to be decidedly worse, and for two weeks had not been able to lift its head from the pillow Emaciation was progressive and the specialist expressed the opinion that the case was hopeless and the child must soon die from marasmus

The history as given by the mother was this Up to eight months of age the child appeared well nourished and in the the best of health About this time it became fretful, grew pale and began to lose flesh Purple spots appeared over its shoulders, back and thighs, which suppurated and many of them were lanced, leaving marks similar to the pitting of smallpox The lower extremities were painful on being handled and the child ceased to move them voluntarily Its diet from birth had been Mellin's food exclusively The mother had lost her ability to nurse on account of multiple abscesses of her breasts at a previous birth

At this time the child was very anemic and much emaciated, weighing but thirteen and a half pounds It could not lift its head nor move its body or thighs, and was handled on a pillow The right femur and left scapula were perceptibly swollen Dentition was delayed The upper and lower middle incisors only were erupted and these were almost hidden by spongy ecchymotic gums In the roof of the mouth was a purplish tumor with an eroded apex The fetor of its breath was marked The body was bathed in sweat The stools were hard and variegated in light drab and dark slate colors, with an offensive odor like those of a carniverous animal The child cried with pain on being handled and was fretful and wakeful during the nights This array of symptoms completed a picture of pitiful distress

Treatment —The food was changed at once to fresh cow's milk and barley flour as a basis Orange juice and raw scraped beef were given daily, which the child took with the greatest avidity Scraped apple and tender sprigs of fresh lettuce and cabbage were also allowed by way of variety A cool sponge bath at 75 degrees with gentle friction was given every morning for its tonic effect To change the character of the stools and disinfect as far as possible the intestinal tract, calomel tablets, one-tenth grain, every two hours, and a powder composed of guaiacol carbonate, one-sixth grain, and protonuclein, one grain every four hours, were ordered given Hydroleine was administered three times daily, for its alterative and reconstructive properties The improvement even in so short a time as twenty four hours was gratifying and astonishing At the end of forty-eight hours the character of the stools were changed and the fetor of the breath had disappeared and the child was inclined to amuse itself After the fourth day it could lift its head and its nights were restful At the end of the first week all traces of spongy gums and sore mouth had disappeared and it began to laugh and crow and exercise its legs and thighs and no longer dreaded handling At the end of the second week it had gained one pound, could lift its feet above its head for the first time in several months All remedies, except hydroleín and occasional doses of mild chlorid, were now discontinued A soft-boiled egg with rolled cracker was allowed every other day alternating the scraped beef Third week, anemia has disappeared Can sit alone Has erupted upper lateral incisors Three weeks ago there was no sign of these teeth Is taken out daily for exercise Fourth week, has gained in weight, rolls about on the rug and tries to creep Discharged cured and returned home at end of six weeks A change like this after six months of helplessness and untold suffering seems little less than magical

The points of interest in this case are The suppuration of the hemorrhagic cutaneous lesions, which the family physician diagnosed and treated as eczema, the swelling of the femur and scapula and slight curvature of lumbar region, diagnosed and treated for six weeks by a noted orthopedist as rickets, and lastly the rapid recovery under antiscorbutic treatment

The foremost problem in the consideration of every disease is how to prevent it Scorbutus is a preventable disease How shall we guard against and limit this recently diagnosed and apparently increasing disorder? We will not find it in the homes of the poor, or among the laboring classes, so often as among the well to do and in the houses of affluence, for the mothers in the commoner walks of life more uniformly suckle their babes, and this is prophylaxis Barlow says "In no single case at the time of the malady has the child been breast fed "

1 Woman herself should be physically prepared for better motherhood so that she may be capable of yielding her offspring the only food nature intended for it

2 Mothers should be impressed with the fact that there is no perfect substitute for breast milk, and that next to the right of being well born, the babe has an inalienable right to nature's food, and no trivial excuse or surmountable difficulty should hazard its life or health

3 Where for any reason the breast milk is inadequate, or has entirely failed, the nearest approach to it is to be found in the modified cow's milk of our modern laboratories, or the home modification of cow's milk after the plans given by Rotch in his most valuable recent work on pediatrics

4 Above all, *no continuous* administration of any sterilized, Pasteurized, peptonized or condensed milk, or any dry commercial foods should be given to the *exclusion of fresh or raw elements of diet* In what this antiscorbutic property consists, which is found in fresh foods, and lacking in the artificially prepared and manipulated foods, is not yet determined, but it is more than likely that the important offices performed by the normal germs of the gastro-intestinal tract in the complicated processes of digestion are incapable of being completed with artificial food, and thus putrefactive changes in imperfectly digested pabulum, lead to auto-infection and malnutrition

There is a "borderland condition," as Barlow terms it, without detected lesions, a sort of *scorbutic malnutrition*, which the physician should be on the look-out for in every artificially fed infant I believe scorbutus exists in incipient forms of malnutrition to a greater degree than is commonly apprehended The causes must be in operation for a more or less prolonged period to produce apparent lesions In its typical form it is rarely seen before the latter third of the first year Happily for most bottle fed infants they are saved from the active stages of the disease by the timely admission of certain elements of antiscorbutic diet It is to this class I would call especial attention The physical condition of the child during the first eighteen months of its existence is of the utmost importance to its future It is the period of most active and rapid development, and malnutrition now will weaken its vital powers of resistance for its whole life

Some of the premonitory symptoms are fretfulness, aversion to being handled, crying out as if in pain when lifted, tenderness of the lower limbs and indisposition to move them, and progressive anemia The diet should be investigated and appropriately regulated and the parents or others having the care of the child should be instructed as to the necessities of the case for intelligent cooperation

If every artificially nourished babe could be carefully inspected and its diet harmonized with the cardinal principle pointed out by Barlow, Northrup, Rotch and others, a great army could be saved from premonitory malnutrition, of which the fully developed scorbutic forms but a small contingent

2036 Indiana Avenue

DISCUSSION ON PAPERS OF DRS BELL AND BURR

Dr W A Dixon, Ripley, Ohio—The use of the stomach and rectal tube can not be too much impressed upon the profession Children are badly fed, and after the stomach is once loaded and the bowel is disturbed by food that is doing injury or damage, you must or *ought* to use the stomach and rectal tubes I use them a great deal and to a very great advantage Dr Burr's timely paper had reference to artificial feeding I believe if the profession is cursed by anything at all, it is by the impression abroad that children must be fed by the bottle and by these artificial foods I believe we are running in the wrong direction as a profession when we permit and submit to the weaning of the child, the taking away from the breast simply because we have inflammation of the breast We ought to interfere if we are the attendant at the time of confinement, or, if we are the family physician, we ought to anticipate these troubles, we ought to step in beforehand and announce to the mother that she must be prepared to nurse her child, and portray to her all the troubles that follow if it is nursed artificially Nothing has brought more sorrow to me in my practice than to treat children fed artificially, and hence I lay great stress upon impressing upon the mother the importance of being prepared to nurse the child at the breast, and I take great censure upon myself if I allow mammitis to follow

Dr Foster, Deering, Me —I would like to ask Dr Bell, before he goes, how often he irrigates the stomach?

Answer In the case of imperfect digestion, the process of irrigation should be continued until you have obtained a degree of digestive power The stomach should be tested to see that it digests the material, and the irrigation should be continued until the stomach can digest the food given Of course, using the predigested food assists this process

Dr J A Work, Elkhart, Ind —In this process of irrigation, I would like to ask the Doctor, does he propose to empty the stomach of everything or only undigested food?

Answer It should be cleaned thoroughly at the time of the irrigation

Dr J A Work—How is he to do that when the child is fed upon milk and has a high temperature and the milk is coagulated in the stomach? How is he going to get the food [illegible] without emesis?

Answer The contraction of th [illegible] ill thro beside the tube as well as thro [illegible] If y reason to believe you have large clots there it is well to over distend the stomach first The tube then is used as an irritant and as a means to get other fluid in

Dr Burr—Why does the Doctor choose very warm water in preference to cold water, especially in pyrexia?

Answer I referred to warm water in cases of depression from the cholera infantum The hot water gives a better cleansing effect You may have, of course, elevation of the temperature, but in cholera infantum you have no especial elevation of temperature and sometimes you have an abnormally low temperature And certainly in those cases you would use the hot water But outside of that there is no special reason for using hot water

Question What temperature?

Answer I should use water about 110 degrees If I wanted an effect in the reduction of temperature, I should use it cooler than that

Dr Burr—I believe with Dr Bell that the irrigation of the stomach and colon is of the utmost importance in all these cases of malnutrition and indigestion, which are almost synonymous terms But I have found the application of cold water externally and internally to be far more stimulating than hot water I would use the cold water in colonic flushings because you can get up peristalsis better with it The peristalsis better empties the bowel, perhaps, than the flushing itself The peristaltic action brings matter away from far up the colon It is a question whether you often get these tubes above one of the flexures of the colon or rectum Now, if you have infantile convulsions, which are in a large majority of cases induced by indigestion and autoinfection and its explosive effects on the nerve centers, which are so unstable in infancy, then the cold water is doubly important I know nothing more irrational than what I find day after day of the method of plunging the child into a hot mustard bath and putting something on the abdomen, but neglecting the important feature of first emptying the colon The first step in my mind is a full cool bath if there is pyrexia, and pyrexia you will often find is the cause of the convulsions The over heated blood, of course, is another effect of the poison We have the poison first, pyrexia next and convulsions third, following the effects upon the nerve centers We should use the cold bath to reduce the temperature first, then the colonic flushing and then the stomach irrigation, and if we think there is something irritating left we should give a good old-fashioned dose of castor oil With the other process we may have convulsion after convulsion I have found sometimes the attending physician present, who has assured me the child has had bath after bath, and I would find the hot water there colored with mustard in evidence and still the convulsions continued Fifteen minutes after rational measures were used the child would be asleep

Dr J A Work—I asked Dr Bell the question about the emptying of the stomach because I believe the first thing we have to do as physicians in any of these acute cases is to remove the cause as soon as possible A physician, unless he studies to do that, is not worthy the name My friend has just given us a key note I have practiced that for twenty-seven years and am more confirmed every day in the belief that we are not to simply administer medicine, but we are to study the cause and remove it That is the reason I asked the question In these neurotic cases let us get back to the first cause, or as near as possible to the primary cause, of all the trouble When I am called to a case of acute irritation of the intestines or stomach with rise of temperature, I first ascertain how the child has been fed I then want to know about the elimination, because we know there are only four emunctories, or "sewers" *as I explain to the friends of the patient*, the bowels, skin, kidneys and lungs, and I inquire about all these "sewers," whether they are in proper condition or not If I find the bowels have not moved sufficiently recently, I first secure an evacuation of the bowels and then depend largely, as to what to do next, on what is the condition of the contents of bowels passed After the bowel is thoroughly cleansed I give the bath, not so much to reduce the temperature, but I have the patient given a washing with soap and water, for nine children out of ten need it at that juncture After they are washed thoroughly I have them put in a well ventilated room, and in almost every case the excitement is gone and the patient is calm, easy and on the road to recovery immediately

Now as to the use of the rectal tube I believe if we come to consider ourselves as an animal machine, that every thought and motion wears us out and that by reason of this we have to take food and drink, and in our younger days we are active and the activity causes increased circulation and activity of all the body, but as we grow older we are not as active and we need prompting of the elimination We notice the little boys and girls, say 10 years old, wear out about ten pairs of shoes to our one, which shows they are more active, and they do not have the same need of prompting of the elimination Some ask, if they begin the use of the enema or purgative, won't they have to use it all their life But, I ask them, hadn't they better use it all their lives than to be invalids all their lives I believe there are cases in which nothing else will do but to have elimination, either by the rectal tube or enema, every day, twice a day Here is a proposition I want to lay down, upon which I have practiced and which I have demonstrated The four emunctories I have mentioned must each do its work and we must not depend upon one to do the work of the other, but each must be allowed or caused to do its own work within the proper physiologic time

Dr H E Garrison, Dixon, Ill —There is one point brought out which I would like to notice, and that is the use of castor oil in cases of infantile convulsions I have experimented with it for a long time I had one boy whose diet I could not control and he would have convulsions now and then Sometimes he would go two months before a convulsion would occur I finally decided to give him Rochelle salts for I could not get him to take castor oil I gave the salts in lemonade whenever he became a little constipated Eight months have now passed without the child having a convulsion

Dr C W Foster, Deering, Me —I have been somewhat interested in these papers, but it seems to me the ideas expressed have been along lines of practice in which I am not specially interested It has been my experience usually, when I have been called, the child has had its fit or convulsion, and very rarely do I see a second or third one They usually remain quiet until I can get a movement of the bowels by a big dose of calomel or castor oil, and certainly I have seen or thought I have seen children that have been quieted and have gone along very nicely with that method It seems to quiet the nervous system very well In regard to the nursing of children, spoken of in Dr Burr's paper, in my region it is not so difficult to get healthy mothers to nurse their children, but the great difficulty arises often, I think, in urging the mother to nurse her child We have a great many women who are mothers who are not physically qualified and I do not believe such mothers are fit to nurse their children I believe it is often better to have the children fed with artificial food, cow's milk, than to have them nursed by these sickly, tuberculous women I am, myself, a sample of a cow fed baby, for I came from a tuberculous family One thing about cow's milk, overlooked by a good many, is the difference in the milk supply of large cities and small cities and villages I live in a small city and I believe the milk there is better when it is delivered than that milked last night or early this morning, twenty miles from the city, left at the depot, collected by milk men, mixed together in an ice chest and delivered to morrow morning I do not believe such milk is good when it is deliv ered That is one difficulty in feeding babies on cow's milk in the city I do not believe milk churned a mile is as bad as milk that has been churned five or ten miles In my early life I was on a railroad fifteen months I had one of these delightful gravel trains, where we had to have our meals on the train I found the milk at the first meal had become well buttered The stomach irrigation is delightful where it can be carried out In small cities or country, where the patient may be several miles away and we have to put up with the ordinary mother, nurse or help, it is very difficult to wash out the stomach every time the child is fed, or even to give it good rectal injections It seems to me the sytematic bathing, the use of warm and cold baths, can be carried on in hospitals and cities, where competent help is plentiful, but such treatment is hardly applicable where we can not get competent nurses

Dr E D CHESBRO, Providence, R I —One point in regard to infantile scorbutus is the shrinking, anxious expression, which was particularly interesting to me This particular symptom to which I have referred, was very striking This child developed no subperiosteal hemorrhage so far as I could see, but she had repeated attacks of epistaxis The Doctor referred to treatment effecting speedy cure, but perhaps the case he reported would have recovered just as quickly with a change of diet It is a question in my mind whether drugs exert very much influence in these cases

Dr A C COTTON, Chicago—We have had some talk on scurvy lately Last year Dr Love had something to say, and the year before something was said upon scurvy In illustrating a statement that he made, a medical friend of mine, in speaking of fads and the tendency to follow when anybody starts anything, said when anybody reads a paper everybody begins for the first time in his life to find he has a few cases of the same kind, rather intimating we are not all honest, and he used scurvy as an illustration I think it has struck every one here we hear a good deal more of scurvy than we used to and we see a good deal more of it than formerly There is a good reason for this The country is overrun with artificial foods, persistently advertised by the manufacturers and also by physicians, who ought to know better In some whole communities exclusive artificial baby feeding is adopted and the effect is seen in the development of scorbutic symptoms Formerly they used exclusive milk diet, and then they died of acute milk poisoning, but they did not have scurvy I think it is Kerr, writing upon milk, in his description says it contains living cells, aside from the proteid substances we have been in the habit of recognizing and dividing into lact albumin and caseinogen and these living cells are directly absorbed and used in the animal economy of the infant, but are destroyed by heat, even heat sufficient to Pasteurize it He also says, as we have heard before frequently, that the heat coagulates the albumin We all know that even when heated to 160 degrees, some of the lact albumin is coagulated and the emulsion is thicker than before Knowing these two facts, I do not think we should say we do not see why infants should not develop scorbutus or malnutrition on cooked food and not on raw food I do not know anything more interesting to me than the discussion Dr Burr brought out so well in his very concise paper

Now as to the point mentioned by Dr Burr and Dr Dixon If a woman were to come into your office and ask you to abort her, because it is a good deal of trouble and expense to have a baby and she does not want to undergo the responsibilities of maternity, I suppose about the first question you would ask her would be Who recommended you to come to me on this errand? That is my first question, because my curiosity is excited But it does not take long to disabuse her mind of her error in coming to you It is possible you may show her to the door a little frigidly Now why not show an attitude similar to that toward the woman who does not want to nurse her child? She may say she had trouble nursing her previous child, but why should we not take just as high ground concerning maternal feeding as we do in regard to this other crime? It is a crime to allow the mother to wean her baby, unless there is some thoroughly scientific reason for it Of course we do not want a tuberculous mother to nurse her child We have not paid enough attention to inducing the mother to produce a proper food for her baby We should make the mother a good milker by feeding her properly and taking care of her Rotch has said some good things in his book in regard to the management of lactation

It may be I lack the delicacy of touch in passing the tube, but I find in the majority of cases the sigmoid flexure is an insuperable obstacle It has been said, instead of doing as Dr Bell suggested, to pass the tube so *easily* right up to the transverse colon and then turn on the water, if you turn on the water while introducing the tube the introduction of the tube will be facilitated

Dr DANIEL H CUNNINGHAM, Chicago—As to passing rectal tubes, I have always used about a No 8 or 9 hard rubber catheter, turning on the water immediately upon entering the rectum and directing the catheter with the finger, and have been sometimes, not always, able to pass the sigmoid flexure

Dr BURR—The paper I presented on "Infantile Scorbutus," was intended to emphasize the fact that we have a great deal of incipient scorbutus which does not arrive at the point of characteristic appearances, so that it can not be recognized as scorbutus but only as a tendency toward it the child will eventually, perhaps become scorbutic unless attention is paid to change in its diet The question of feeding children in the city and in the country are two different questions Our city born, city fed and bred children labor under many disadvantages the country children know nothing about The majority of country mothers are far beyond the city mothers in the point of health When I say a child must be breast fed, I presuppose a healthy mother I would not advise breast feeding from a mother suffering from tuberculosis, syphilis, or other constitutional disease But I believe we should make the healthy mother feel she is a criminal if she denies the child nature's food, unless there are, as I stated in the paper, unsurmountable difficulties The question of getting pure milk in cities is one of the most difficult problems In our city we have found necessary a well enforced ordinance, fining milk men for furnishing bad milk, and every month some of them are brought up and fined As to the remarks of Dr Chesbro, about the expression of fear and timidity on the part of the child, I mentioned that in the paper What is the cause of the fear? The child dreads to be touched Why? Because its little joints are sore, perhaps there is hemorrhage already under the periosteum When you find that expression you should look out for scorbutus Let that be one of your early symptoms or warnings with reference to the condition of the child's nourishment Malnutrition is an omnibus word, in one child it may lead to rickets, one form of malnutrition, in another scorbutus, another form of malnutrition, in another to petit mal or epilepsy, in which the malnutrition gives expression in another way, in another it may predispose to tuberculosis Anything which lowers the power of vital resistance will lead into one of these numerous roads from health to invalidism I do not wish to emphasize the medical treatment of scorbutus Undoubtedly the orange juice, raw milk and meat would have worked a wonderful change in the child I did believe the calomel and guaiacol of value in the first few days With reference to what Dr Cotton said about fads, the diagnosis of the condition in this child was not a fad The child was under the care of a physician from eight until twelve months of age, before it was brought to Chicago A number of scars were found over the body, from the breaking down and formation of little abscesses in numerous places But while the commercial men are distributing more and more their chromo advertisements of artificial foods and the mothers get recommendations from their family, friends and neighbors, as well as from the press and even some physicians, scorbutus will continue to increase The tendency is a wrong one and we ought to call a halt with all the emphasis possible

As to colonic flushing, I have repeatedly found my rectal tube or one of these large catheters, which serves the purpose admirably, doubled up and extruded forcibly from the bowel It is often utterly impossible to pass it beyond the sigmoid flexure A little postural change may assist matters very much For instance, by having the hips elevated you may facilitate the accumulation of water in the colon and assist the peristalsis I prefer cool water, at 80 or 75 degrees

---

A CASE OF CHLOROMA

Read in the Section on Ophthalmology at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5-8 1896

BY S C AYRES, M D
CINCINNATI OHIO

It is possible that the subject of chloroma is as new and rare to many of you as it was to me when the case I have to report came into my hands It only came into my service at the Ophthalmic Hospital because the neoplasm had invaded the orbits and produced a marked exophthalmus In the *American Journal of Medical Sciences* for August, 1893, appears a paper entitled "Chloroma and its Relation to Leukemia," by Dr George Dock, of Michigan, in which he reports a case He has examined the literature of all languages and collected, including his own, seventeen cases of chloroma

Edward Ludwig, aged 7, was admitted to the Ophthalmic Hospital May 18, 1893 His parents are living and in good health There are five other children in the family, all of whom are healthy

Previous history —He has always been a bright, intelligent boy and has never suffered from any serious illness He has had repeated attacks of parotitis (?) and the present trouble seems to have followed one of these attacks He at first complained of pain in both orbital regions and at the same time both eyes seemed to be more than usually prominent After a week or more, his mother noticed some impairment of his hearing, which slowly increased The exophthalmus increased more rapidly He became very weak and somewhat emaciated, and complained of a severe pain in the left foot, on account of which he was unable to walk

Upon his admission into the hospital both globes were very prominent, but the right more so than the left It was with difficulty that he could close the lids of the right eye over the ball The corneæ are clear and there is no impairment of vision The conjunctivæ of both eyes are red and chemotic The motility of the eyes is unimpaired In the upper and outer portion of the right orbit can be felt a dense, inelastic growth which protrudes beyond the edge of the bone A similar growth can also be felt in the left orbit, but not so pronounced The optic papillæ are somewhat pale, but there are no other alterations in the fundus of either eye His hearing is so much impaired that he has to be spoken to in a loud tone Pulse 120 per minute, temperature normal There is no lesion of any of the cranial nerves Muscular power and sensation of both upper and lower extremities normal Pressure on the sole of left foot produces pain, but there is no redness or swelling in this locality

May 21 The proptosis of the right eye has increased, but that of the left is apparently slightly less There has developed a swelling in both temporal regions They are rounded and elastic, without any sensation of fluctuation

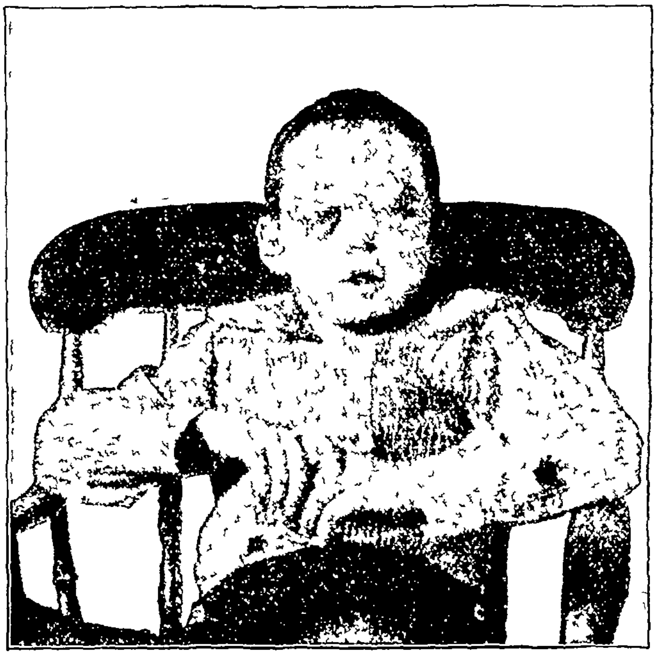
May 23 Protrusion of both eyes increased, corneæ hazy and covered with inspissated mucus

May 27 Temperature normal, pulse 120 Patient complains of some difficulty of micturition, later on, retention of urine Both corneæ are quite opaque The swellings in the temporal regions more pronounced There has developed a hard, firm swelling in the region of each parotid gland Intelligence good, hearing somewhat improved Pain in foot still present No appetite The exophthalmus of both eyes increases day by day Both globes are now forced beyond the palpebral fissure

June 2 Condition worse in all respects He has had a severe hemorrhage from the conjunctiva of the right eye

June 5 Died this morning as result of hemorrhage from the conjunctiva of the right eye

Three days before death, blood pale and watery Staining according to the Ehrlich method showed a marked increase in the number of white blood corpuscles, the increase being due principally to the number of multinuclear cells, while the small lymphocytes and those white cells characteristic of splenic and myelogenic leukemia are not increased Eosinophile cells are sparingly present, not above 2 per cent The examination of the blood at this time justifies the diagnosis of leucocytosis only, and not leukemia Furthermore, an examination of the patient revealed no enlargement of the lymphatic glands except those of the neck



The postmortem examination was made about twenty-four hours after death Body fairly well developed and nourished, postmortem rigidity well marked, the upper and lower extremities normal No evidence of subcutaneous hemorrhages Marked swelling of the lymphatic glands about the neck Both eyeballs protrude to such an extent that they are only partly covered by the eyelids, sloughing of both corneæ Traces of blood about the eyes, mouth and nose Mucous membrane of mouth swollen, teeth covered with blood To the touch the lymphatic glands are firm and resisting, with no sign of fluctuation A small nodular infiltration over the right parietal bone near the median line On cutting through this swelling it was found to be situated beneath the periosteum, and although there was no evidence of its having arisen from the bone, the latter was at this point remarkably thin No trace of inflammation or infiltration of the pia mater or the brain The brain was found to be intensely anemic On removing the brain the orbital plates were seen to bulge upward owing to the pressure from within After removing the very thin orbital plates, both cavities were found filled with a firm, solid and somewhat elastic mass of a light greenish color, which pushed the eyeball forward This mass was removed with some difficulty although only at one point did it seem to be firmly adherent to the periosteum lining the orbital cavity Here the bone was somewhat eroded Behind, the new growth extended to the sphenoidal fissure, surrounding but not involving the optic nerve In front and above, the newly formed tissue extended to and a little beyond the orbital arch On superficial examination the new growth seemed to be confined to the orbital cavities, a further examination showed this not to be the case, for the cancellous tissue of the sphenoid and the petrous portion of the temporal bones were softened and infiltrated with a dirty greenish-yellow fluid, looking very much like pus On the left side in the petrous portion of the temporal bone was an area in which the bone tissue was completely destroyed and filled up with a material such as was found in the orbits, differing from it only by being of a more dirty greenish-yellow color and not quite so firm The lymphatic glands presented the same appearance in section as did the tumors of the orbits

Equally as interesting proved the further examination of the new growth On having placed the tumor in alcohol, the color disappeared entirely within twelve hours On the other hand, the specimen kept within a tightly corked bottle, still retains the greenish color, in fact, the color has become even more marked Some of the fresh fluid taken from the interior of the sphenoid bone was examined, but revealed only the presence of large numbers of small corpuscles, fat globules and granular detritus

The section of the tumor after being hardened in alcohol and ether seemed to justify the diagnosis of sarcoma, the cells being almost entirely of the small round variety, none or very few spindle cells, and remarkably little intercellular substance, no large blood vessels, but numerous lymph spaces Furthermore, the small round celled infiltration extended into the upper eyelid down to the yellow elastic cartilage

The seat of the tumor, the peculiar color, the history of the growth, the remarkable involvement of the lymphatic glands, the results of the microscopic examination, make this case one of a few that have been put on record under the head of chloroma cancer vert, the green cancer of the French

Whether the form of tumor should be called a sarcoma, whether it is of the so-called connective tissue variety, or on the other hand, as Dock would seem to believe, a peculiar condition arising in the course of true leukemia, the tumors being regarded in this case as lymphomata—these are questions which the future must decide Dock and a number of others have found by an examination of the blood that they were contending with true leukemia My examination of the blood, as already described, showed a remarkable increase of white blood corpuscles, but they were indicative only of a marked leucocytosis, and not a true leukemia This examination was made three days before death However, there is still a great deal of obscurity about leukemia as to its true nature, and when we consider that some writers have suggested the name of sarcoma of the blood for this disease, we can not wonder that in the case of chloroma the pathologic conditions found were suggestive of leukemia

I am greatly indebted to Dr Greiwe for the above report of the postmortem and of his microscopic examination of the growths His views, while they may differ from other investigators', are founded on examinations made of the neoplasm removed from different localities It is very unfortunate that the portmortem did not include the thoracic and abdominal cavities A more complete examination might have thrown some light on the tissues invaded by this strange disease

In all the prominent diagnostic points my case seems to correspond with the one reported by Dr Dock, as well as most of those he has so carefully collected

Color —In color it was a yellowish-green, or perhaps a pea green It did not vary much in the different localities, but was more pronounced in the larger masses

Consistency —This differed in different localities It was homogeneous and without fibrous septa I have described the cut masses as presenting a smooth, shining, jelly-like appearance

Involvement of periosteum and bone —Most of the cases show involvement of the periosteum, and in this case it was marked, but more than this an actual softening of the bone Dr Greiwe in his report says that "the cancellous tissue of the sphenoid and the petrous portion of the temporal bones were softened and infiltrated with a dirty greenish-yellow fluid, looking very much like pus" On the left side in the petrous portion of the temporal bone was an area in which bone tissue was completely destroyed and filled up with a material such as was found in the orbits differing from it only by being of a more dirty greenish-yellow color, and not quite so firm

Duration —From the report of the mother it seems that she noticed the exophthalmus only four weeks before she brought him to the hospital He died in two weeks after he was first seen Allowing two weeks to elapse in which the changes were not detected by the parents, the disease ran its course in the short period of two months After he was first seen the growth was exceedingly rapid and could be noticed day by day

Hemorrhage —Epistaxis is mentioned as occurring in some of the cases of chloroma reported In Ludwig's case there was severe hemorrhage from the conjunctiva of the right eye This occurred in my patient the day before he died, and then on the following day recurred with such violence as to destroy his life

Retina —The eyes were carefully examined and no swelling of the optic discs and no retinitis was found The discs were pale and anemic, but not atrophied His vision was good In a short time the cornea became so involved that further inspection of the fundus was impossible

Exophthalmus —This was pronounced and was the first symptom that attracted the attention of his parents The engraving shows his appearance a day or two after he was first seen It was made from a photograph taken by Dr Arch Carson, to whom I am indebted for his interest in the case The exophthalmus increased slowly in both eyes, but more in the right, and in a week from the time he was first seen the proptosis was so great that he could not close the eyelids, and in consequence the cornea ulcerated

Exciting causes —There is no known exciting cause in this case, but his illness followed an attack of parotitis His mother said he had had several attacks of so-called parotitis It is not probable that these attacks were true mumps, but precursors of the development of the disease

Deafness —Deafness was a marked feature varied slightly in severity from day to day, and it was always necessary to speak to him in a loud tone He had no catarrh and there was no otorrhea The drum membranes were not examined

Dr Dock says "From what we do know of the natural history of leukemia and of chloroma we can see the analogies of the diseases We can say that chloroma is a lymphomatous process similar in its clinical features to leukemia and pseudo-leukemia Our ignorance of its precise relations depend partly on the fact that our knowledge of chloroma is very incomplete, partly on the indefinite nature of leukemia and pseudo-leukemia "

OBSCURE CASES OF OPTIC NERVE ATROPHY OF CEREBRAL ORIGIN

Read before the Section on Ophthalmology at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5-8 1896

BY CHARLES W KOLLOCK, M D

CHARLESTON, S C

Affections of the brain proper that might cause atrophy of the optic nerve are very numerous, but in a majority of cases the disease which produces the optic neuritis causes the death of the patient before atrophy takes place, or can be recognized by the aid of the ophthalmoscope The cases who can survive the disease sufficiently long for the nerve to become atrophied are usually too obscure in many instances for human ingenuity to explain and though the neurologists of to-day are wonderfully accurate in their knowledge of this complex organ—the brain —still in very many cases their conclusions must be purely problematical When we remember that a tumor growing in the brain tissue may produce optic neuritis in one case, and in another death may occur without an eye symptom having been seen, we may readily understand the difficulties of accurate diagnosis

Lesions at the base of the brain will be followed by characteristic symptoms according to the parts involved and compressed, but it does not follow that atrophy will occur merely because there happens to be a growth, an aneurysm, or even a thickening of the meninges at this locality Meningitis, when not fatal, often involves the optic nerve and its sheaths and atrophy gradually supervenes, but such cases are not obscure The history will often give a thorough insight as to the cause of the consequent atrophy

Lesions of the corpora quadrigemina are rare, and cause blindness, loss of pupil reflex, strabismus and nystagmus when the anterior pair, and loss of coördination when the posterior pair are effected But both pairs usually become involved and when a defective action of the same branches of the oculomotor nerves on both sides is seen it is more characteristic of quadrigeminal disease than is neuritis, choked disk, or atrophy

Atrophy from anemia is more common after severe hemorrhage rather than from inanition Von Graefe usually found atrophy coming on some time after hemorrhage took place and Schweigger says, that the loss of blood and disease of the optic nerve are wholly unexplained and can not be due to simple anemia Jaeger has described atrophy of the optic nerve that follows hemorrhage Soon after the hemorrhage occurs the vision becomes indistinct, it may improve or become worse according to the nutrition of the patient, but after repeated hemorrhages amblyopia increases and vision is lost The disk is pale and bluish in appearance, the sclerotic band is broad, and the remainder of the eye ground is very pale and the vessels smaller than normal Fries says that 35 per cent are due to hemorrhage of the stomach and intestines, 25 per cent uterine, 25 per cent from abstraction of blood, 7 3 per cent due to epistaxis, 5 2 per cent to bleeding wounds and 1 per cent to hemoptysis and urethral hemorrhage Tumors pressing upon the cerebral blood vessels and anything that interferes with the circulation in the brain may cause atrophy of the optic nerve, but it is more than propable that death would occur before the atrophy became apparent

Embolism occurs generally in young persons and is caused usually by a diseased condition of the heart valves, rarely from thrombosis of the veins of the lower limbs, and still more rarely from myocarditis, that causes a rupture of the endocardium It may also be caused by an atheromatous degeneration of the inner coats of the aorta, and form gangrenous or other processes in the lungs, by tumors that press upon and produce inflammation, and finally form wounds The middle cerebral artery is most often plugged, which does not immediately produce atrophy but more likely a softening of the brain that may eventually involve the optic nerve and cause atrophy

Thrombosis comes from atheromatous degeneration of vessels and is more frequent after middle life There are generally prodromal symptoms and it is at times very difficult to distinguish between this lesion and cerebral hemorrhage, but recovery rarely takes place after the former The mental powers gradually fail and the patient finally becomes demented Atrophy is rare from this lesion

Cerebral aneurysm —Optic neuritis is uncommon after this lesion and therefore atrophy is also rare, except perhaps in some cases where there may be direct pressure upon the optic nerves or chiasma Optic neuritis has been occasionally seen when there was an aneurysm of the internal carotid and was then double Loss of sight in one eye, sometimes extending to the other, with, or especially without, optic neuritis, with or without loss of smell on the side affected, occurs in aneurysm of the internal carotid or anterior cerebral artery, and the distinction between the two depends on the presence or absence of paralysis of the other nerves of the eye ball first affected which occurs especially when the aneurysm is of the internal carotid Cerebral aneurysms occur usually between the ages of 10 and 60, rarely before or after, and as often before 40 as after, and more frequently in males than females

Cerebral abscess occasionally causes optic nerve atrophy by extension of the inflammation to the nerve or its involvment by the consequent softening of the tissues Abscess of the brain is generally due to injury or suppurative inflammation and is more common among males than females 42 5 per cent are caused by ear disease, 24 per cent by injury and the remainder are due to diseases of the nose, orbit, non traumatic causes and tumors It occurs in males and females in the proportion of 3 to 1 1 to 9 years, 24 cases, 10 to 19 years 48 cases, 20 to 29 years, 72 cases 30 to 39 years, 29 cases, 40 to 49 years, 26 cases 50 to 59 years, 16 cases, 60 to 69 years, 7 cases, 70 and over, 1 case

Optic neuritis is less common than in tumor Location does not affect the neuritis and loss of sight is probably due to neuritis as vision is rarely affected by the abscess itself

Multiple sclerosis occurs at all ages but more frequently in the first half of adult life, between the ages of 20 and 30 years It may affect any portion of the brain, hence the symptoms vary The cranial nerves are often affected, especially the first, second, third, fifth and seventh Loss of muscular control is a common and early symptom, movements are peculiar and jerky but cease when the parts are at rest Nystagmus is very common The "eye symptoms are frequent and important The optic nerve may suffer in various ways There may be impairment of sight in one eye or both, often with an irregular contraction in the field of vision, and without at first any visible changes in the optic nerve to account for it This condition depends upon the development of an islet of sclerosis in one or both optic nerves, or in the chiasma It may progress almost to complete blindness of one eye After a time secondary atrophy supervenes, and can be seen with the ophthalmoscope, occasionally the atrophy is preceded by slight neuritis, when sclerosis is near the eye ball In some cases again there is a primary atrophy of the optic nerves, exactly like that which occurs in tabes, with a similar failure of sight, proportioned to the visible alteration in the nerve Both eyes usually suffer, but one is often affected earlier than the other This complication is, according to my own experience, rather more frequent than the form first described, and is of much pathologic interest " There is at times loss of accommodation, less frequently light reflex and the pupils may be unequally dilated

Bulbar paralysis or labio-glosso-pharyngeal paralysis occurs generally in the second half of life and in males oftener than females The causes are obscure, sometimes mental depression and anxiety, exposure to cold, debilitating influences and injuries, as blows upon the back of the neck Optic nerve atrophy is of rare occurrence in this disease and of course when it occurs the symptoms of the disease would be a guide in diagnosis

Paralysis of the insane; general paralysis —Vision is frequently affected by this disease, the ophthalmoscope showing choked disk or consecutive atrophy according to the stage of the affection General paralysis is a disease of the well-to do, the rich rather than the poor, and occurs generally among those who live a busy, hurrying life rather than among those who reside in rural districts and lead quiet lives It is often seen in the highly educated, in males oftener than females and about the prime of life Hot climates, certain pursuits and excessive sexual indulgence are known to be exciting causes Child-bearing and over indulgence in alcoholic liquors may also be a cause It frequently follows or is associated with locomotor ataxia The symptoms of this disease are so well known that it should not be difficult to diagnose the cause of the optic nerve atrophy In addition to the general symptoms there may be at times dilatation of the pupils myosis usually occurring at an early stage, but a difference in the size of the pupils is still more definite The "Argyll-Robertson pupil' is often seen, these symptoms usually occur in other diseases of the brain and are chiefly valuable as indicating central disease The cause of this disease is "a progressive degeneration of the encephalo spinal nervous system attended by subacute inflammatory changes in the membranes of the brain and cord' Atrophy of the optic nerve in this disease may be distinguished from that caused by tumor of the brain, syphilis of the brain, etc , by the absence of the symptoms that indicate those lesions and especially from the latter by the failure to get improvement by the use of mercury and iodid of potassium Treatment is of no avail in this form of atrophy

Brain tumors cause diffused symptoms, headache, vertigo, vomiting, general epileptiform convulsions, apoplectiform attacks, psychic disturbances and choked disk Choked disk is found more frequently (54 per cent) in cases when the tumor involves the corpora quadrigemina Direct pressure on the optic tract causes atrophy, at times, without choked disk Tremors and localized spasms are valuable diagnostic signs, because, first, they are more frequent with tumors than other lesions, and second, they are more frequent in the cortex, third, more frequent in the motor zones In more than one-third of all cases localized spasms and contractions exist at some time during the disease and when present they indicate localization in the cortex oftener than elsewhere, next the corpus striatum and optic thalamus Paralysis is gradual and distinguishes it from hemorrhage Tumors of the corpora striata, corpora quadrigemina and lenticular nuclei cause hemiplegias more slowly than hemorrhage Disturbances of vision are very frequent as symptoms of brain tumor 1, atrophy of optic nerve following choked disk, 2, deviation of the eye ball or eye lids from isolated or combined paralysis of the nerves supplying the ocular muscles, the third, sixth and seventh, 3, amblyopia, or amaurosis, resulting from direct affection of the optic nerve in its course through the cranium, or at its cerebral centers, the mode of development being, therefore, almost precisely analogous to that of paralysis of any of the nervous tracts by direct compression The optic chiasma or nerve is liable to pressure from tumors arising from the base of the cranium or from the hypophysis, and also from the peduncles Hemiopia is produced when one tract or one side of the chiasma is compressed Tumors of the thalamus do not often cause blindness Tumors of the corpora quadrigemina have a much larger percentage of blindness than those of any other part and those of the cerebellum come next

---

THE DIFFERENTIAL DIAGNOSIS BETWEEN SIMPLE GLAUCOMA AND OPTIC NERVE ATROPHY

Read in the Section on Ophthalmology at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Georgia May 5 8 1896

BY B ALEXANDER RANDALL, M D
Ophthalmic and Aural Surgeon to the Methodist and the Children's Hospitals, etc
PHILADELPHIA, PA

At first thought little difficulty would seem to present itself in differentiating simple glaucoma from optic atrophy, and in the majority of cases any careful student ought to succeed A table can easily be constructed, giving the typical like and unlike symptoms with such clearness of "deadly parallel columns" as to make the tyro sure that only a blockhead could err Yet some or all of our differentiating signs are at times lacking or doubtful, anomalous or casual complications are encountered, and experience teaches that the best-posted observers are tri times to the uttermost by the uncertainties of some cases And when a case passes from one to another with varying diagnosis, the later student will do well to temper his self-gratulations by remembering that the cardinal symptoms may have been wholly masked before, and better fortune rather than superior skill has given him the advantage

It behooves us, therefore, to study out, with all care, every detail, even in cases that appear perfectly clear, for most of us have had patients in whom at one time no trace of glaucoma has been detected, while shortly afterward they have presented themselves with so marked a stage of the affection as to convince us that exhaustive study ought earlier to have recognized it I shall not soon forget two ladies sent me, about the same time, by one physician, each of whom had full development of glaucoma in the left eye when they returned two years later One had rainbow vision, that made my study exhaustive, though vain for other symptoms, the other had no suggestions of it Both were irretrievably neglected, when seen again Such cases passing into other hands must arouse doubts of the competency of the earlier adviser, unless there is full and frank communication with him On the other hand, optic atrophy may strongly suggest glaucoma and lead to a tentative or positive suggestion of iridectomy which the subsequent history shows to have been groundless

In simple glaucoma and optic atrophy we may usually find the contrasted symptoms of the following table, but it must never be forgotten that they may be wholly absent, or obscured if present

TABULATION OF SYMPTOMS

Simple Glaucoma	Optic Nerve Atrophy
Tension increased	Normal
Cornea hazy and anesthetic	Normal
Anterior chamber shallow or obliterated	Normal
Iris atrophic and discolored	Normal
Pupil dilated and sluggish or fixed	Small or dilated (Robertson)
Reflex yellowish green, "glaucous"	Normal
Perforating vessels dilated and tortuous	Normal
History of pain and obscurations	Painless loss
Unilateral character usual at first	Bilateral generally
Limitation of field usually to nasal side	Concentric limitation
Color fields commensurate to form fields	Disproportionate loss
Rainbow vision about lights	No halos
Knee jerks unaffected	Often lowered or lost
Optic disc cupped, margins overhanging	Dished, margins shelving
Halo of choroidal atrophy usual	Halo rarer
Nerve tissue greenish in shadow	Nerve bluish gray
Arteries and veins pulsating	Arterial pulsation rare

The cardinal symptom of increased tension is variable and often uncertain Hardly any two observers will exactly agree as to the tension of an eye, and a rigid sclera, a tense eyelid or a rude touch may easily cause error Palpation had better be done with the index fingers of both hands applied to one eye at a time and then transferred to the other for comparison In doubtful cases it may be done upon the uncovered sclera, but it is usually better to have the patient look very far down and palpate above the tarsal cartilage If there are intermissions in the symptoms, we may expect to find corresponding falls of the tension to the normal With a shrinking patient the surgeon must be gentle and not over-endowed with thumbs The superficial corneal haze, which gives it a slight "pin-stuck" appearance like ground-glass or a mirror that has been breathed upon, may be a very delicate change and, like the anesthesia, demand close observation to detect it It is doubtless due to edema of the epithelium and pressure upon the nerves Though most marked near the pole, it is nearly uniform, in contrast to more localized keratitic changes Individual differences in the depth of the anterior chamber, with a tendency to shallow with advance of life, must be taken into account, and the pressing forward of the lens is not usually very marked, but the appearance of the iris is usually quite characteristic Altered color, vague detail of the surface or irregularities of structure and a general suggestion of atrophy are rarely lacking, and can easily raise a question as to iritis present or past, by the peculiarity of some of the changes So too the pupil, semi-dilated and fixed as a rule, oval oftener than round, at best sluggish and imperfect in action — it is generally more abnormal in even the beginning of glaucoma than it becomes in any but the last stages of optic atrophy The peculiarities of action to accommodative stimulus but not to light, which Argyll-Robertson pointed out, the hemianopic reflex of Wernicke, the consensual action of an iris otherwise immobile, are rare in any glaucomatous phase, and may be determinate of the character of the nerve degeneration which we generally have to diagnosticate largely on negative data, by exclusion The yellowish-green reflex, often seen in the pupil of the glaucomatous eye, may have some counterpart in the opalescent haze of the lens in the patient with atrophic nerves, who is usually well advanced in life and has more or less arcus senilis and other diminutions of the transparency of his media Yet it joins in the formation of the external picture of glaucoma which the skilled observer can often recognize at a glance, although analysis of its details shows each of them so vague as to bring doubt as to its real existence Rarely lacking, however, to complete the picture and demonstrate the congestion of the ciliary vessels is the turgid, dark fullness of the perforating veins as they emerge from the sclera, several millimeters back from the cornea and meander beneath the conjunctiva Many conditions of ciliary congestion are marked by the undue prominence of these vessels, but in none of the active conditions are they as marked as they usually are in simple glaucoma Other injection of the anterior segment, such as may be great in the acute and subacute glaucomatous attacks, may be wholly lacking in all phases of simple glaucoma, and yet the observer will hardly fail to receive an impression of congestion, out of proportion to the expanse of these vessels

The history ought to help the diagnosis greatly, by the statement of pain in the eye, hemicrania or "neuralgia," coincident with the periods of obscuration and heralded by rainbows around the light Both affections are likely to be bilateral, but in optic atrophy the second eye follows but little behind the other in its decline whereas years may intervene before the glaucoma that has blinded one eye manifests itself in the other

Mensuration of the visual field should never be neglected, and although its showings are never to be accepted as pathognomonic, much can generally be learned from the charts thus obtained Color-vision is generally much lowered in optic atrophy, red and green even wholly lost or presenting very restricted areas of perception, with scotoma regions, where the recognition is weak, if not quite lost The form-field is more commonly restricted uniformly in the spinal and some of the cerebral cases, although hemianopsia and quadrant defects are not unusual, and may be very helpful in localization of the underlying lesions In glaucoma the general form-field suffers proportionately more and may be narrowed down, more especially on the nasal side until mere central vision remains, and the patient "sees as through a gun barrel"

The knee jerks and other tendon and muscle reflexes are well worthy of careful study in a number of our eye cases, but especially in any where plantar numbness, lancinating pains in the extremities and imperfect station or coördination suggest spinal disease None of these defects are to be expected in glaucomatous conditions, although it is not impossible to have glaucoma attack an individual giving such evidences of lesion of the cerebro-spinal axis

It is to the ophthalmoscope especially that we turn, however, for our diagnosis in many of these uncertain cases Here the picture may be unmistakable, when much was doubtful in all other directions Yet we can be over-confident as to its help, and find a picture that is almost typical of glaucoma when none is present, or that gives no confirmation to a diagnosis that is unmistakable in spite of such negative findings It is easy to make a set of diagrams, as does Fuchs, to define the difference between physiologic, atrophic and pressure excavation of the nerve head, but in fact we may meet combinations or transpositions of such appearances Jaeger's admirable atlas gives us some of the puzzling findings, while others have probably never been reported The total cup, with overhanging edge and greenish shadow, may seem typically present in cases with normal fields and perfect central vision, and we look again in a vain effort to see where healthy nerve fibers can find a place at the margin of such a disc So, on the contrary, we may find not only acute, but chronic glaucomas, in which neither the ophthalmoscope nor even anatomic study later, under the microscope, can demonstrate superficial cupping nor underlying depression of the lamina cribrosa Most trying is such an inconclusive or contradictory finding in such cases where one eye has already been lost by unmistakable glaucoma, and the other is affected, but with a condition too little defined to make us positive in deciding either for or against iridectomy

NOTE —Numerous original illustrations of the typical and the contradictory appearances of eye grounds, fields and anatomic sections were thrown upon the screen with the stereopticon

SPONGE GRAFTING IN THE ORBIT FOR SUPPORT OF ARTIFICIAL EYE

Read in the Section on Ophthalmology, at the Forty seventh Annual Meeting of the American Medical Association at Atlanta Ga May 5 8 1896

BY E OLIVER BELT, M D

WASHINGTON D C

PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY HOWARD UNIVERSITY AND OCULIST AND AURIST TO FREEDMEN'S HOSPITAL

To a skilled oculist the ordinary enucleation of an eyeball is one of the simplest operations he is called upon to perform, and yet there are some cases in which so much of the conjunctiva is destroyed by careless or ignorant operators, that it is impossible for an artificial eye to be worn afterward This is very annoying to a patient, and we can not blame him if he never forgives the doctor who has so afflicted him Such cases emphasize the fact that it is the duty of the surgeon not only to operate skillfully for the immediate relief desired, but he should do everything in his power to prevent disfigurement, and when an organ or limb can not be restored to usefulness, he should at least obtain the best cosmetic results possible After an eyeball has been removed and an artificial eye inserted, very frequently it is not as prominent as the natural eye It has a sunken appearance which attracts attention, at once, to the fact that the eye is artificial To remedy this defect has been a problem for ophthalmologists for years

One of the most satisfactory operations heretofore practiced is that known as Mule's operation, which consists in the evisceration of the contents of the eye, and the insertion of a hollow glass globe in the sclerotic This is sewed in, and proves fairly satisfactory, but there is some danger of the globe being broken, and occasionally the stitches come out and the globe escapes There is also the risk of sympathetic ophthalmia, where the entire eyeball is not removed To obviate these difficulties and at the same time secure a full orbit, I have devised a method of sponge grafting which seems to meet the requirements without the disadvantages of other methods

The operation is a simple one and is performed as follows The eyeball is removed by the ordinary method under strict asepsis After all hemorrhage is arrested the socket is washed out with a formalin solution, 1 to 1,000, followed by sterilized salt solution A globe of fine, soft sponge, about three-fourths the size of the eyeball, previously sterilized in 5 per cent formalin solution and rinsed in the salt solution, is then inserted into the socket, or capsule of Tenon The conjunctiva is brought together and sewed with rat-tail sutures The eyelids are then closed with compress and bandage In a few weeks the sponge is filled with new tissue, which in time becomes firm, solid flesh, making a full orbit and a fine support for the artificial eye The sponge fibers are apparently absorbed

I have performed this operation in five cases with fairly good results in all, but union of the conjunctiva has not been firm enough to prevent some of the stitches from breaking or cutting out and the wound gaping In future cases, to relieve this strain on the conjunctiva and to obtain good motion of the eye, I think of uniting the opposing recti muscles with rat-tail sutures, and then the conjunctiva over that by the purse string or subcutaneous suture By this method we should get union by first intention, good motion of the stump and a full orbit There seems to be no danger from infection of the sponge, for in two cases the eye was removed for panophthalmitis Not only has this operation advantages over other methods [illegible] recent cases, but in old cases in which the eye [illegible] removed months or years ago, where there is [illegible] sunken appearance of the artificial eye, the [illegible] might be reopened and a sponge inserted

Since making my investigation, I find that [illegible] J Hamilton of Edinburgh practiced spong[illegible] for old ulcers in 1880, since which time [illegible] physicians have tried it in fresh wounds [illegible] other similar conditions that skin graft[illegible] used in However, I can not find in [illegible] literature in the library of the Sur[illegible] office any mention of sponge being [illegible] suggested and tried,

Case 1 —E L, colored, aged

Hospital in the spring of 1895, suffering from a ruptured eye ball (from a blow). Sight was entirely destroyed, and as the injury extended entirely across the cornea and through the ciliary region I advised removal of the eyeball, to which she consented. As she was willing to stay in the hospital as long as necessary and I could keep her under observation, I decided to try the insertion of a small sponge in the socket, with the hope that new tissue might form through it, as was reported to have occurred with a sponge accidentally left in the body during an operation. Accordingly, after removal of the eye, a globe of fine sponge was inserted and sewed in the socket. The sponge had been sterilized by boiling. After a few days the stitches came away and the sponge was exposed; however, there was no tendency for it to come out. There was considerable discharge and the orbit and sponge were cleansed as frequently as required. In two or three weeks about half of the sponge separated and came away. I found the remaining portion filled with new tissue and presenting a healthy granulating surface. The patient left the hospital soon after and was not seen again until a few days ago when I found a moderately well filled orbit, the wound was entirely closed and appeared to be covered with conjunctiva.

Case 2.—April 7, 1896. A. B., right eye ruptured (eight days previously by blow) through cornea and ciliary region. Eye full of pus. Enucleated under anesthesia, socket cleansed with formalin solution, 1 to 1,000. Sponge (sterilized with 5 per cent. formalin solution) inserted and stitched in with silk sutures. April 15, sutures out, wound gaping and sponge showing full length of fissure. May 5 about half of the sponge separated and came away, the balance filled with new tissue. June 3, socket full of new tissue and wound closed. Artificial eye inserted, has good motion and no sunken appearance of orbit.

Case 3.—April 13. C. T., aged 30, eye lost seven years ago. Eyeball shrunken. Eye removed under anesthesia. Socket cleansed with formalin solution, 1 to 1,000. Sponge inserted and stitched in with rat tail sutures. April 28, temperature normal all of the time. No suppuration. Wound healed by first intention. Smooth stump. April 30, one or two stitches out, sponge showing for one fourth inch, but seems to be filled with new tissue. June 3, wearing artificial eye. Orbit full, has not a sunken appearance, and motion of eye good.

Case 4.—April 23. A. J., aged 30. Stuck fork in left eye one week ago. Panophthalmitis. Eye enucleated under anesthesia. Socket washed with formalin solution, 1 to 1,000. Sponge inserted and stitched in with catgut and rat-tail sutures. April 30, some stitches out and sponge showing. May 5, fissure closed again with rat tail sutures. May 7, all stitches out again. June 3, wound gaping and sponge showing, but adherent all around and new tissue filling three fourths of sponge.

Case 5.—April 25. M. B., aged 30. Right eye lost by purulent ophthalmia several months ago. Eye enucleated under anesthesia. Socket cleansed with formalin solution, 1 to 1,000. Sponge inserted as usual and rat-tail sutures used. May 5, doing well, but some stitches out. June 3, nearly the entire sponge is filled with new tissue and the wound closing up.

A CASE OF TOTAL BLINDNESS, POSSIBLY DUE TO AN OVERDOSE OF QUININ.

Read in the Section on Ophthalmology at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY H. BERT ELLIS, B.A., M.D.
LOS ANGELES, CAL.

August 8, 1895, I was called to J. W., a man 34 years old. After repeated questioning of the patient and his sister, the following disconnected, incomplete and probably somewhat inaccurate history was elicited.

The young man was an accountant in the employ of one of the Texas railroads and had been with them for years although for some time he had been an opium, whisky and tobacco habitué. The first habit he had contracted as a result of the use of opium during an attack of dysentery. Four years ago, he had gone to an institute and had been cured of these habits, but quickly lapsed into them again, excepting that he never renewed the use of tobacco.

I was unable to find out definitely the amount of morphin and whisky that he used daily. His own statement was to the effect that he had been taking about 7 grains of morphin daily. This statement was probably inaccurate, for judging from the amount it was necessary to give to keep him reasonably quiet, at the time I was called, he certainly could not have been taking less than from 10 to 20 grains in the twenty-four hours, and probably more for some months, and of whisky he used from one pint to one quart daily.

In October, 1894, when suffering from malaria, he had been given by a physician 120 grains of quinin in twenty-four hours in four doses. In a very short time he was totally blind in both eyes, but this condition lasted only about two weeks, after which there was a gradual return of vision, so that he resumed work on his books, and was able to continue at intervals by aid of an assistant (for his vision never became good) till February, 1895, since which time he had not been able to see anything, except to distinguish a bright light occasionally. There was no history of concurrent deafness.

During June and July he had been living with a woman who was an opium habitué and she had kept him constantly saturated with morphin, till his sister brought him to Los Angeles.

The patient, five feet, nine or ten inches tall, was extremely emaciated, weighing about 103 pounds, his normal weight had been from 145 to 150. He had the marked opium cachexia and puffiness of lower lids. There was almost complete loss of the cutaneous and deep reflexes the knee jerk being entirely absent. The bowels were sluggish, and the urine very scanty, ten to twelve ounces in twenty-four hours. He was practically demented, his memory so defective that he could not sustain a conversation.

The pupils were so small that it was quite impossible, in his helpless condition, to make a satisfactory ophthalmoscopic examination, without producing mydriasis, which I did with a weak solution of sulphate of atropin, and found the fundi presenting very small deviations from the normal. Both nerves were pallid and the arteries and veins, though relatively normal, were both slightly reduced in size, no other changes could be detected.

The morphin was gradually diminished and codein substituted, the whisky slowly reduced, so that by November 1, he was taking no morphin or whisky.

At different times, trional in 15 grain doses, chloralamid 30 grains, chloral and bromids 20 and 30 grains, and hyoscyamin 1-30 grain were given to quiet him. Sulphate of strychnin was administered, in gradually increased doses from 1-60 to ⅓ grain three times daily, hypodermically, in the temples. The knee jerk and other reflexes returned. Occasionally he would describe quite accurately some object in the room, but these returns of vision were very transient. His intellect improved materially, as did also his physical condition. About November 1, he had two quite marked convulsions, and we decreased the strychnin. The patient died late in December, of bronchitis and edema of the lungs, a condition not unlike senile bronchitis.

Was this a case of toxic amblyopia? and if so, was it due to quinin, morphin or whisky?

NOW is the time to increase the membership in the ASSOCIATION. Let every member send in one or more new names.

THE MEDICAL TREATMENT OF INEBRIETY

Read before the New York State Medical Society at New York City
Oct 15 1896

BY T D CROTHERS, M D
SUPERINTENDENT WALNUT LODGE HARTFORD, CONN

Inebriety is a more complex disease than insanity Its progressive degeneration often dates back to ancestors, to defects of growth, retarded development and early physical and psychic injuries Later, the poison of alcohol, by its anesthetic and paralyzing action, develops more complex states of degeneration, the form and direction of which is very largely dependent on conditions of living and surroundings

The psychic symptoms show progressive disease of the higher brain centers, both masked and open, with degrees of palsy and lowered vitality In insanity many definite pathologic conditions are traceable In inebriety a wider, more complex range of causes appear, the line of march of which is often traceable in more general laws of dissolution Its medical treatment must be based on some clear idea of what inebriety is, and the conditions present in the case to be treated This requires a careful clinical study of the symptoms, tracing them back to causes, and all the varied conditions formative in the progress of the case In such a study, heredity appears as the most frequent early predisposing cause The question then is What conditions of life have been most active in developing these inherited tendencies? How can these conditions be checked and prevented? What means and methods are possible in the rational treatment?

The second class of cases most commonly noted are those due to physical causes These are the physical and mental strains and drains, also injuries both physical and psychic The remedies here are distinct, and the means to build up and restore these defects call for therapeutic skill and judgment A third class of inebriates seem to be due to especially psychic causes, of which mental contagion of individuals, of conditions and surroundings are most prominent

Here another class of remedies and therapeutic measures are required These classes are often combined, and the various causes are blended, requiring more accurate study to determine the leading factors in each case These are conditions which provoke the early use of alcohol, and give form and direction to the progress of the case

The second part of the clinical study of inebriety is the effect of alcohol What injury has it caused? How far has it intensified all previous degenerations, and formed new pathologic conditions and sources of dissolution? Also what organs have apparently suffered most seriously from the drink impulse? and, most important of all, how far is the use of alcohol a symptom or an active cause? Having ascertained these facts, the medical treatment is the same as in other diseases, the removal of the exciting and predisposing causes, and building up the body

The first question is the sudden or rapid removal of alcohol If the patient is alarmed, and intensely in earnest to abstain, he will consent to have the spirits removed at once If he is uncertain, and has delusions of the power of alcohol to sustain life, the withdrawal should depend upon circumstances The removal of all spirits at the beginning of the treatment is always followed by the best results The reaction which follows can usually be neutralized by nitrate of strychnia, one-twentieth of a grain every four hours, combined with some acid preparation Soda bromid, in 50 or 100-grain doses every three or four hours will break up the insomnia, and cause sleep the first two nights

The withdrawal of spirits should always be followed by a calomel or a saline purge, and a prolonged hot-air or hot-water bath, followed by vigorous massage Hot milk, hot beef tea and in some cases hot coffee, are very effectual If the patient persists in a gradual reduction of the spirits, strychnia 1 20 of a grain should be given every two hours The purge and hot bath should be given every day while the spirits are used The form of spirits should be changed from the stronger liquors to wines and beers Some of the medicated wines are useful at this time, or spirits served up in hot milk There is no danger of delirium from the withdrawal of spirits, particularly where baths and purging are used freely The two conditions to be treated at this time are poisoning and starvation The system is saturated with ptomains from alcohol, and suffers from defective digestion The nutrition is impaired, and organic growth retarded Saline or calomel purges with baths meet the first condition, foods and tonics the second Not unfrequently the withdrawal of spirits reveals degrees of brain irritation and exhaustion, that are practically manias and delirium, or dementia and melancholia The essential treatment is to regulate the nutrition and elimination, then arsenic, strychnin, phosphates and iron will comprise the chief remedies that are found most useful

Many of the chronic cases of inebriety reveal dementia when spirits are removed, others show well-marked paresis, or tuberculosis Symptoms which were attributed to the action of alcohol are found to be due to previous degenerations In one case the demented talk and conduct while using spirits burst into marked dementia when the drug was withdrawn In another case, the wild, extravagant conduct of the inebriate appears in paresis when free from spirits

The removal of alcohol is often followed by tuberculosis, not suspected before, which apparently starts from some trivial cause and goes on rapidly to a fatal termination

Rheumatism and neuritis are forms of disease which frequently appear after the withdrawal of spirits Diseases of digestion are common, also diseases of the kidneys The latter is usually masked and bursts into great activity when alcohol is removed These and many other organic diseases suddenly come into view, and whether they have existed, concealed by the anesthetic action of alcohol, or have started up from the favoring conditions of degeneration caused by spirits, are not known The therapeutic requirements must reach out to meet all these unsuspected disease states which may appear any time

The removal of spirits in all cases reveals conditions of both physical and psychic degeneration that call for a great variety of therapeutic measures

The next question is to ascertain the special exciting causes and remove or build up against them In the periodic cases the early favoring causes of the drink storm are often reflex irritations from [illegible] nutrition, exhaustion and excessive [illegible] Later a certain tendency is formed for [illegible] deranged nerve energy in alcoholic impulses for relief This periodicity is often due to causes which can be studied and prevented by remedial measures In certain cases nutrient and sexual excesses are followed by a drink storm In another, exposure to malarious influences, where the disease has existed for a long time before, brings on the craze for drink In other cases, constipation, overwork, neglect of hygienic care of the body, irregularities of food and sleep, emotional excitements or depressions are followed by an alcoholic craze A vast range of psychic causes have been noted Thus, a residence on the seashore or in high altitudes, on mountains, provokes his thirst for spirits and removal to higher or lower planes is followed by a subsidence of it Many persons never use spirits except in large cities, or at special exciting gatherings, or on holidays and festive occasions Here evidently some defect of the brain exists, either organic or functional, which should be reached therapeutically Literally, many of these cases have been cured by change of surroundings as well as medicines

While the ostensible object of medication is to stop the drink craze, this is as far from being curative as the suppression of pain by a dose of opium Conditions which cause the disordered nerve force to concentrate in cravings for the anesthesia of spirits, are to be neutralized and prevented before a cure can be expected

The use of narcotics and drugs to check the desire for spirits at the beginning is temporary and always uncertain Opium, chloral and cocain given freely at this time often simply changes the drink craze for these drugs, which are used in the place of spirits ever after

The return of the drink impulse at regular or irregular intervals is in most cases preceded by premonitory symptoms, which enable the physician to use preventive remedies In certain cases calomel and saline cathartics, with prolonged baths, rest, or exercise, according to the requirements of the case, have been found curative

Various cinchona tonics, free from spirits, and iron preparations are often useful Large doses of strychnin seem more valuable after the full development of the morbid impulse, given when spirits are discontinued Some of the various coca compounds on the market have a strong influence in breaking up the drink storm

In a certain number of cases patients are unconscious of the approach of the drink storm and are difficult to treat But when they realize its coming and seek assistance the task is easier The general principle of treatment is sharp elimination through all the excretory organs and the use of mineral tonics, changes of diet and living, particularly a study of the exciting and predisposing causes, and their removal When the drink paroxysm has passed away, then radical constitutional remedies are to be used The history of syphilis calls for mercury, arsenic and potassium Defective nutrition requires a study of the diet best suited to build up the tissues

Entailments from other diseases, as malaria, rheumatism and various neurotic affections, require appropriate remedies

Tinctures of any form are dangerous The susceptibility to alcohol is so great that the smallest quantity is felt, although it may not be recognized Where spirits are taken continuously the system is always depressed all functional activity lowered and literal palsy and starvation are present

The removal of alcohol is only a small part of the treatment The demand for alcohol is a symptom of this progressive degeneration Given remedies to produce disgust for the taste of spirits, or to break up the cravings for it, are not curative Apomorphia, mixtures of atropia, hydrastin, and a great variety of allied remedies, are all dangerous, while apparently breaking up a symptom of the disease present they often literally increase the degeneration by their irritant narcotic properties and further depressing action on the organism The indiscriminate use of these, and allied drugs, in the various specifics for inebriety, is the most dangerous empiricism It is the same as opium or other narcotics for pain in all cases, irrespective of all conditions and calling the subsidence of the pain a cure Thus in the following cases a periodic after a gold-cure treatment developed into acute dementia, which ended fatally In others epilepsy, acute mania, pneumonia, rheumatism, nephritis, followed from the chemic suppression of the drink impulse In all probability the narcotics used were active, contributing causes to the particular organic disease which followed

The masked character of inebriety makes it dangerous to use narcotics beyond a certain narrow limit Cases which have been subjected to active drug treatment to suppress the desire for spirits are feebler and more debilitated than others Those who have taken the so-called specifics are marked examples and whether they use spirits again or not are always enfeebled and pronounced neurotics In all these cases there is so wide a range of causes and conditions that specific routine treatment is impossible

Strychnin has recently come into prominence and is a useful, valuable drug In some cases where the spirits are withdrawn its action is pronounced as both a tonic and stimulant Given in 1-30 grain doses four times a day, for a few days at a time, then discontinued, or given in larger doses for a shorter time, the results are usually good In some cases certain susceptibilities to the action of strychnia are noticeable and where the drug is taken to prevent the drink attack it sometimes rouses it, seemingly precipitating the condition which it is supposed to prevent This is often anticipated in the muscular tremors and nerve twitchings that evidently come from strychnia when used even in small doses

Strychnia should never be given alone, except immediately after the withdrawal of spirits At other times, combined with cinchona or other vegetable tonics, is an excellent tonic Care should be used to watch its effects on the motor nerves, and be sure that the patient is not unusually sensitive to it Belladonna, atropia, cannabis indica hyoscyamus and drugs of this class have a limited value and should be used with great caution in states of irritation following the withdrawal of spirits They are best given in combination with other drugs for a brief time and in particular cases The bromids are valuable in the same way and in the same conditions, only in much larger doses than mentioned in the text-books From 50 to 100 grains to a dose are requisite, always accompanied with baths and never continued more than two or three days Coal-tar preparations are of uncertain value as narcotics, but may be used in certain cases with good results The various mineral and vegetable acids are almost indispensable in selected cases and often can be given a long time as tonics

In the treatment of cases after the paroxysm is over, frequent changes of the form of the tonics are most valuable Iron, phosphorus, arsenic, potassa and bitter vegetable tonics should be alternated, with free intervals, for periods of months The various derangements of the system should be watched and treated with appropriate remedies and every case should be constantly under medical care The facts of the case having been studied, the question of where the medical treatment can be applied to the best advantage must be determined from the case and its surroundings

If at home the physician must have full control and his directions carried out implicitly When the drink paroxysm appears the course of treatment must be prompt and exact In one case the patient goes to bed and is secluded from all sources of excitement, in another he is sent away to the country and among strangers, in a third case a few days' residence in a hospital or asylum under the care of a physician is sufficient Hospital treatment, with its exact care and physical and psychic remedies continued for a long time give the strongest promise of permanent restoration Wisely adapted medical treatment, based on a careful study of each case, makes it possible for the family physician to treat these cases, in the early stages, with success
